The Journal

OF THE

American Medical Association

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES BY

AUSTIN SMITH, M.D.

VOLUME 159 SEPTEMBER-DECEMBER, 1955

AMERICAN MEDICAL ASSOCIATION, CHICAGO 10

OF THE AMERICAN MEDICAL ASSOCIATION—1955-1956

Headquarters of the Association, 535 N. Dearborn St., Chicago 10

	Erie, Pa.
H. Murray	Napa, Calif.
rd D. Hill	Raleigh, N. C.
al Manager, George F. Lull	Chicago
Moore	Chicago
Delegates, E. Vincent Askey	Los Angeles
ouse of Delegates, Louis M. Orr	Orlando, Fla.

BOARD OF TRUSTEES

J. P. Price, Florence, S. C., 1956; James R. Reuling, Bayside, N. Y., 1957; James R. McVay, Kansas City, Mo., 1957; Edwin S. Hamilton, Kankakee, Ill., 1958; Gunnar Gundersen, LaCrosse, Wis., 1958; David B. Allman, Atlantic City, N. J., 1959; F. J. L. Blasingame, Wharton, Texas, 1959; L. W. Larson, Bismarck, N. D., 1960; Thomas P. Murdock, Meriden, Conn., 1960; the President and the President-Elect.

Editor, Austin Smith	Chicago
Assistant Secretary, Ernest B. Howard	Chicago
Business Manager, Mr. Thomas R. Gardiner	Chicago

JUDICIAL COUNCIL

Walter F. Donaldson	Bakerstown, Pa., 1956
H. L. Pearson Jr., Chairman	Miami, Fla., 1957
G. A. Woodhouse	Pleasant Hill, Ohio, 1958
J. M. Hutcheson	Richmond, Va., 1959
Louis A. Buie	Rochester, Minn., 1960
George F. Lull, Secretary	Chicago

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Guy A. Caldwell	New Orleans, 1956
John W. Cline	San Francisco, 1956
F. D. Murphy	Lawrence, Kan., 1957
H. G. Weiskotten, Chairman,	Skaneateles, N. Y., 1957
Victor Johnson	Rochester, Minn., 1958
L. S. McKittrick	Brookline, Mass., 1958
C. T. Stone Sr.,	Galveston, Texas, 1959
W. A. Bunten	Cheyenne, Wyo., 1959
J. M. Faulkner	Boston, 1960
Harlan English	Danville, Ill., 1960
Edward L. Turner, Secretary	Chicago

COUNCIL ON MEDICAL SERVICE

C. E. Wertz	Buffalo, 1956
R. L. Novy	Detroit, 1957
R. B. *Chrisman, Jr.*	*Miami, Fla., 1958*
A. C. Scott Jr.	Temple, Texas, 1958
Joseph D. McCarthy, Chairman	Omaha, 1959
H. B. Mulholland	Charlottesville, Va., 1960
Walter B. Martin	Norfolk, Va.
Elmer Hess	Erie, Pa.
David B. Allman	Atlantic City, N. J.
Mr. Thomas A. Hendricks, Secretary	Chicago

COUNCIL ON CONSTITUTION AND BYLAWS

L. A. Buie, Chairman	Rochester, Minn., 1956
Warren W. Furey	Chicago, 1957
Stanley H. Osborn	Hartford, Conn., 1958
Floyd S. Winslow	Rochester, N. Y., 1959
B. E. Pickett Sr.	Carrizo Springs, Texas, 1960
E. S. Hamilton	Kankakee, Ill.
Elmer Hess	Erie, Pa.
E. Vincent Askey	Los Angeles
Louis M. Orr	Orlando, Fla.

COUNCIL ON PHARMACY AND CHEMISTRY

(Standing Committee of Board of Trustees)

Carl A. Dragstedt	Chicago, 1955
Isaac *Starr*	*Philadelphia, 1955*
Joseph Hayman	Boston, 1955
E. M. K. Geiling	Chicago, 1956
Elmer M. Nelson	Washington, D. C., 1956
Henry K. Beecher	Boston, 1956
Torald Sollmann, Chairman	Cleveland, 1957
James P. Leake	Washington, D. C., 1957
A. C. Curtis	Ann Arbor, Mich., 1957
W. C. Cutting	San Francisco, 1958
O. O. Meyer	Madison. Wis., 1958
M. H. Seevers	Ann Arbor, Mich., 1958
T. McP. Brown	Washington, D. C., 1958
Joseph Stokes Jr.	Philadelphia, 1959
Perrin H. Long	Brooklyn, 1959
W. G. Workman	Bethesda, Md., 1959
H. Eagle	Bethesda, Md., 1959
H. D. Kautz, Secretary	Chicago

COUNCIL ON SCIENTIFIC ASSEMBLY

(Standing Committee of Board of Trustees)

L. W. Larson	Bismarck, N. D., 1955
Carl A. Lincke	Carrollton, Ohio, 1955
Michael E. DeBakey	Houston, Texas, 1956
Samuel P. Newman	Denver, 1957
J. R. McVay	Kansas City, Mo., 1957
Henry R. Viets	Boston, 1958
Charles H. Phifer	Chicago, 1958
Stanley P. Reimann	Philadelphia, 1959
Alphonse McMahon, Chairman	St. Louis, 1959
T. G. Hull, Secretary	Chicago

COUNCIL ON MEDICAL PHYSICS

(Standing Committee of Board of Trustees)

O. Glasser	Cleveland, 1955
Shields Warren	Boston, 1955
Derrick Vail	Chicago. 1955
Frank R. Ober	Boston, 1956
D. M. Lierle	Iowa City, 1956
W. W. Coblentz	Washington, D. C., 1957
George M. Piersol	Philadelphia, 1957
M. A. Bowie	Swarthmore, Pa., 1958
Arthur L. Watkins	Boston, 1958
W. J. Zeiter	Cleveland, 1958
F. H. Krusen, Chairman,	Rochester, Minn., 1959
Anthony C. Cipollaro	New York, 1959
Felix Butte	Dallas, Texas, 1959
Ralph E. DeForest, Secretary	Chicago

COUNCIL ON FOODS AND NUTRITION

(Standing Committee of Board of Trustees)

Clement A. Smith	Boston, 1955
Robert Jackson	Columbia, Mo. 1956
George R. Cowgill	New Haven, Conn., 1956
W. H. Griffith	Los Angeles, 1957
William J. Darby	Nashville, Tenn., 1958
C. A. Elvehjem	Madison, Wis., 1958
John B. Youmans	Nashville, Tenn., 1958
L. A. Maynard	New York, 1959
Grace Goldsmith	New Orleans, 1959
Charles S. Davidson, Chairman	Boston, 1959

COUNCIL ON INDUSTRIAL HEALTH

(Standing Committee of Board of Trustees)

Lloyd E. Hamlin	Chicago, *1955*
Robert A. Kehoe	*Cincinnati, 1955*
W. P. Shepard, Chairman	New York, *1956*
M. N. *Newquist*	New York, *1956*
P. S. Richards	Salt Lake City, *1957*
J. H. Sterner	Rochester, N. Y., 1957
R. T. Johnstone	Los Angeles, 1958
L. C. McGee	Wilmington, Del., 1958
C. F. Shook	Toledo, Ohio, 1958
J. N. Gallivan	East Hartford, Conn., 1959
V. C. Baird	Houston, Texas, *1959*
Oscar A. Sander	Milwaukee, 1959
C. M. Peterson,* Secretary	Chicago

COUNCIL ON NATIONAL DEFENSE

(Standing Committee of Board of Trustees)

A. A. Brindley	Toledo, Ohio, 1955
C. P. Hungate	Kansas City, Mo., 1955
Stafford L. Warren	Los Angeles, 1956
Herbert B. Wright	Cleveland, 1956
R. A. Benson	Bremerton, Wash., 1957
Perrin H. Long	Brooklyn, 1957
Roscoe L. Sensenich	South Bend, Ind., 1958
Harold C. Lueth	Evanston, Ill., 1958
Harold S. Diehl, *Chairman*	*Minneapolis, 1959*
Richard L. Meiling	Columbus, Ohio, 1959
Mr. Frank W. Barton, Secretary	Chicago

COUNCIL ON RURAL HEALTH

(Standing Committee of Board of Trustees)

F. A. Humphrey	Ft. Collins, Colo., 1955
N. H. Gardner	E. Hampton, Conn., 1955
A. T. Stewart	Lubbock, Texas, 1956
H. A. Randel *	Fresno, Calif., 1956
W. J. Weese	Ontario, Ore., 1957
W. A. Wright	Williston, N. D., 1957
F. S. Crockett, Chairman	Lafayette, Ind., 1958
G. F. Bond	Bat Cave, N. C., 1958
C. S. Mundy	Toledo, Ohio, 1959
C. R. Henry	Little Rock, Ark., 1959
Mrs. A. Hibbard, Secretary	Chicago

COUNCIL ON MENTAL HEALTH

(Standing Committee of Board of Trustees)

F. M. Forster	Washington, D. C., 1955
H. T. Carmichael	Chicago, 1956
M. R. Kaufman	New York, 1957
W. H. Baer	Peoria, Ill., 1958
L. H. Bartemeier, Chairman	Baltimore, 1958
F. J. Gerty	Chicago, 1958
L. H. Smith	Philadelphia, 1959
G. E. Gardner	Boston, 1959
R. J. Plunkett, Secretary	Chicago

The Secretary, Assistant Secretary and Editor are ex officio members of all Standing Committees

SECTION OFFICERS 1955-1956

Anesthesiology—Chairman, John S. Lundy, Rochester, Minn.; Secretary, Daniel C. Moore, 1118 Ninth Ave., Seattle 1.

Dermatology—Chairman, J. Walter Wilson, Los Angeles; Secretary, C. S. Livingood, 2799 W. Grand Blvd., Detroit 2.

Diseases of the Chest—Chairman, Edward W. Hayes, Monrovia, Calif.; Secretary, John F. Briggs, 350 St. Peter St., St. Paul 2, Minn.

Experimental Medicine and Therapeutics—Chairman, Thomas P. Findley Jr., Augusta, Ga.; Secretary, George E. Burch, 1430 Tulane Ave., New Orleans 12.

Gastroenterology and Proctology—Chairman, Lowell D. Snorf, Evanston, Ill.; Secretary, Everett D. Kiefer, 605 Commonwealth Ave., Boston 15.

General Practice—Chairman, I. Phillips Frohman, Washington, D. C.; Secretary, E. I. Baumgartner, 25 Alder St., Oakland, Md.

Internal Medicine—Chairman, Henry M. Thomas Jr., Baltimore; Secretary, A. Carlton Ernstene, 2020 E. 93d St., Cleveland 6.

Laryngology, Otology, and Rhinology—Chairman, John R. Lindsay, Chicago 44; Secretary, Hugh A. Kuhn, 112 Rimbach St., Hammond, Ind.

Military Medicine—Chairman, H. Lamont Pugh, Washington 25, D. C.; Secretary, Capt. Cecil L. Andrews (MC) USN, Bureau of Medicine and Surgery, Department of the Navy, Washington 25, D. C.

Nervous and Mental Diseases—Chairman, L. M. Eaton, Rochester, Minn.; Secretary, Karl O. Von Hagen, 2010 Wilshire Blvd., Los Angeles 57.

Obstetrics and Gynecology—Chairman, Frank R. Lock, Winston-Salem, N. C.; Secretary, D. Frank Kaltreider, University Hospital, Baltimore 1.

Ophthalmology—Chairman, Albert D. Ruedemann, Detroit 26; Secretary, Harold G. Scheie, 313 S. 17th St., Philadelphia 3.

Orthopedic Surgery—Chairman, William T. Green, Boston 15; Secretary, Frederick R. Thompson, 16 E. 90th St., New York 28.

Pathology and Physiology—Chairman, Roger D. Baker, Durham, N. C.; Secretary, Edwin F. Hirsch, 1439 S. Michigan Blvd., Chicago.

Pediatrics—Chairman, F. Thomas Mitchell, Memphis 5, Tenn.; Secretary, Wyman C. C. Cole, 3011 W. Grand Blvd., Detroit 2.

Physical Medicine—Chairman, Frances Baker, San Mateo, Calif.; Secretary, Walter J. Zeiter, 2020 E. 93d St., Cleveland 6.

Preventive and Industrial Medicine and Public Health—Chairman, Edward P. Luongo, Los Angeles 17; Secretary, Frank Princi, University of Cincinnati College of Medicine, Cincinnati 19.

Radiology—Chairman, Leo G. Rigler, Minneapolis 14; Secretary, Traian Leucutia, Harper Hospital, Detroit 1.

Surgery, General and Abdominal—Chairman, Waltman Walters, Rochester, Minn.; Secretary, Walter G. Maddock, 250 E. Superior St., Chicago 11.

Urology—Chairman, Rubin H. Flocks, Iowa City; Secretary, Thomas A. Morrissey, 40 E. 61st St., New York 21.

* Percentage of tracer dose in thyroid gland 24 hours after administration.
† Percentage of tracer dose per liter of plasma in washed plasma proteins 72 hours after administration.
‡ Protein-bound serum iodine in micrograms per 100 ml.

16 were clinically cured at the time of their report. Of these, one had an uptake of 62%, and four had levels of protein-bound I^{131} of more than 0.3% of the administered dose per liter of plasma. Stanbury and associates in 1952 reported I^{131} studies carried out in Mendoza, Argentina, an area of endemic goiter, under the title of "The Iodine Deficient Human Thyroid Gland." Most of the glands were very large. Uptakes of over 60% were frequent. Recant and Riggs [11] studied 11 cases of nephrosis. In two cases there were uptakes of 75 and 71% even though the basal metabolic rates were low, as were the serum protein-bound iodine values. R. Fraser reported four cases of induced myxedema following resorcinol therapy in persons with high uptakes of I^{131}.

In 1953 Hubble [12] reported on a cretin with an uptake of 61% that could not be released by thiocyanate, indicating that the iodine was bound to protein in the thyroid gland. Taylor reported on two euthyroid subjects with nodular goiters who showed uptakes of 65 and 86% in 48 hours. Burrows and Ross discussed cases of cured hyperthyroidism in patients who had abnormally high uptakes of I^{131} but showed normal uptakes when this was considered in terms of uptake of stable iodine rather than in terms of I^{131} alone. McGirr and Hutchison in 1953 studied 12 cases of "non-endemic goitrous cretinism." Two of these patients had uptakes of 75 and 77% and the accumulated iodine could not be displaced with thiocyanate. Of the 12 patients, 8 had high serum levels of protein-bound I^{131} 48 hours after administration of the tracer dose. These values varied between 0.49 and 1.12% of the administered dose per liter of plasma. Drummy [13] reported uptake studies in 493 euthyroid individuals. Fifty-six of these had large goiters, 18 had multinodular thyroids, and the remaining 38 had diffusely enlarged glands. Of 18 with multinodular goiters, one had uptake of 62%, and 10 of 38 with diffusely enlarged goiters had uptakes of from 50 to 75%. Blood levels of protein-bound I^{131} and protein-bound stable iodine were not recorded. Stanbury, Taylor, and Burrows and Ross found euthyroid patients with high uptakes.

A patient with postoperative myxedema was reported [14] with a basal metabolic rate of –20%, protein-bound iodine level of 1.3 mcg. per 100 cc., an iodine uptake of 21%, and blood levels of protein-bound I^{131} of 0.4% per liter of serum. In 1954 Morgans and Trotter [15] reported two cases studied 9 to 18 days after the discontinuance of iodine therapy to normal individuals. These patients had uptakes of 79 and 87% and had protein levels in the blood of 2.9% per liter of serum. When the same cases were restudied 25 days later all values were normal. Monroe [16] exposed rats to whole body radiation totaling from 500 to 665 r. He found increased uptake and organic binding of I^{131} one day after the x-ray exposure. These changes were no longer present at 7 or 30 days after the exposure. Hutchison and McGirr [17] observed that the uptake and binding of I^{131} in sporadic goitrous cretinism may both be high. On the basis of butyl alcohol solubility they decided the released organically bound iodine was not thyroxin, but they did not further identify it.

COMMENT

A consideration of the literature cited and the observations here recorded can leave no doubt that a not insignificant number of patients with normal or even decreased thyroid function, when studied with I^{131} tracer techniques, yield results "characteristic" of hyperthyroidism. This pitfall has two serious clinical implications already alluded to. The first is that euthyroid patients may be treated unnecessarily by surgery or with I^{131}, and the second is that hyperthyroid patients who have been adequately treated and cured of their disease may be subjected to further treatment and rendered myxedematous. It is our opinion that some of the post-treatment myxedema following I^{131} therapy has been due to the additional use of therapeutic doses of I^{131} administered on the basis of tracer studies alone without regard to the clinical state of the patient. In determining the status of a patient with thyrotoxicosis who has received one or more therapeutic doses of I^{131}, we are convinced that the best guide as to the necessity for further treatment is the clinical state of the patient. The basal metabolic rate and the protein-bound iodine (stable) of the serum are the two best laboratory aids. The I^{131} studies are the least valuable of the laboratory tests in these patients and can be most misleading.

The mechanism of these discordant results is not yet definitely established. We can conceive of several alternatives. The first is that the renal clearance of iodide has been markedly decreased. The fate of the tracer iodide is determined by the relation between the avidity of the thyroid tissue for iodide and the ability of the kidney to clear iodide from the plasma. A marked decrease in this latter function would leave more iodide available for the thyroid and could result in increased thyroid uptake. Simultaneous renal clearance studies were not made in these cases so no final answer can be given, but there certainly were no evidences of renal disease in these patients and we consider this explanation unlikely. A second possible explanation for the increased uptake could be a decrease in the total miscible iodide pool, essentially a decrease in the iodide concentration in the total body water. That this sometimes occurs is indicated by the studies of Burrows and Ross. We think that this is the most likely explanation for increased uptake in euthyroid individuals. The trapping of a given percentage of the tracer represents, as always, a trapping of the same percentage of the total miscible iodide pool. If the iodide pool is reduced, then the total amount of iodide trapped for a given percentage of tracer trapped will be lower than if the iodide pool were normal or high. The clinical state of the patient is determined by the amount of stable iodide trapped and converted to hormone and secreted. The uptake of I^{131} really represents the percentage of the total stable iodide pool trapped in the same period of time. It does not indicate the gravimetric amount of iodine trapped. It is therefore clear that high uptakes of I^{131} can be associated with normal or even decreased uptakes of stable iodide if the stable iodide pool is sufficiently reduced.

[17] Hutchison, J. H., and McGirr, E. M.: Hypothyroidism as an n Error of Metabolism, J. Clin. Endocrinol. **14**: 869, 1954.

We think that the most likely explanation of the high blood levels of protein-bound I^{131} in these euthyroid individuals is the assumption of a reduced hormonal iodine pool in the thyroid gland. If the stored hormonal iodine (thyroxin) is reduced, then a large proportion of this pool must be drawn upon each day in order to maintain the euthyroid state. In other words, a euthyroid individual with a small hormonal pool in his gland has a rapid turnover of this pool even though only the normal amount of hormone is secreted per unit of time. Because the pool is small, the specific activity of the hormone formed and secreted after the tracer dose will be high. Therefore the protein-bound I^{131} level in the plasma will be high even though normal amounts of hormone are secreted each day. The protein-bound I^{127} level of the plasma, a good index of the concentration of circulating hormone, will not be elevated, but protein-bound I^{131} level will be elevated because of the high specific activity of the secreted hormone.

There is good evidence[18] that the lowest thyroidal hormonal pools are found in patients cured of hyperthyroidism, particularly those cured by I^{131}. The large proportion of persons with cured hyperthyroidism that appear in group 2 and 3 of this series confirms this fact and is consistent with the explanation offered above. It is interesting that in group 2 (high uptake—normal protein-bound I^{131}), only 2 of the 33 were previously hyperthyroid, while group 2 (normal uptake—high protein-bound I^{131}) had 46 previous hyperthyroid persons in 51 cases. In group 3 (high uptake—high protein-bound I^{131}), all but 2 of the 29 patients were previously hyperthyroid. The very low thyroidal hormonal pool in these cured patients is the most likely explanation for the "hyperthyroid" protein-bound I^{131} levels.

SUMMARY

Of 113 patients euthyroid during this study, 33 had radioactive iodine (I^{131}) uptakes of more than 55%, but protein-bound I^{131} levels in their plasma were below 0.3% of the administered dose per liter of plasma 72 hours after administration of the tracer dose. Of these 33, only 2 had previously had hyperthyroidism. Although 51 patients had normal uptakes, the protein-bound I^{131} levels in their plasma were over 0.3%. Forty-six of these 51 had been cured of hyperthyroidism. Twenty-nine patients had both increased uptakes and increased plasma protein-bound I^{131} levels, and all but two of these had been cured of hyperthyroidism. The possible mechanisms involved may be related to a reduced iodide pool and a diminished hormonal iodine pool in the thyroid. Awareness of these "false hyperthyroid" results with I^{131} testing will assist the clinician to avoid unnecessary treatment of normal subjects and will prevent further treatment of persons who have been cured of hyperthyroidism with resulting myxedema.

MEDICAL PROBLEMS OF SKIN DIVING

William T. Burns, M.D., Long Beach, Calif.

In the past 10 years since World War II "skin diving" has become an increasingly popular sport. Liberal estimates for the number of individuals participating in skin diving throughout the United States for the year of 1954 are numbered at one million. More conservative estimates number these sports divers between 250,000 and 500,000 persons. Many of the divers belong to skin-diving clubs. In California the Council of Diving Clubs list 125 clubs. Throughout the United States there are an estimated 375 clubs. The average age of the skin diver is about 20 years, with a ratio of about 90% male to 10% female divers. Self-contained underwater breathing apparatus is used by approximately one-third of the divers. Statistics to date have been difficult to obtain, and most have been based on estimates from equipment sales. In Europe skin diving is also popular and continues to increase in popularity as here in the United States. Skin diving anywhere is done principally for fun, whether it be spear fishing or exploration. Professional groups have been organized by states and by certain universities for study of marine life. Other fields, such as underwater photography, geology, salvage, archeology, and mining, are sure to take more and more divers in the future below the surface of all bodies of water to study and develop one of the last remaining frontiers.

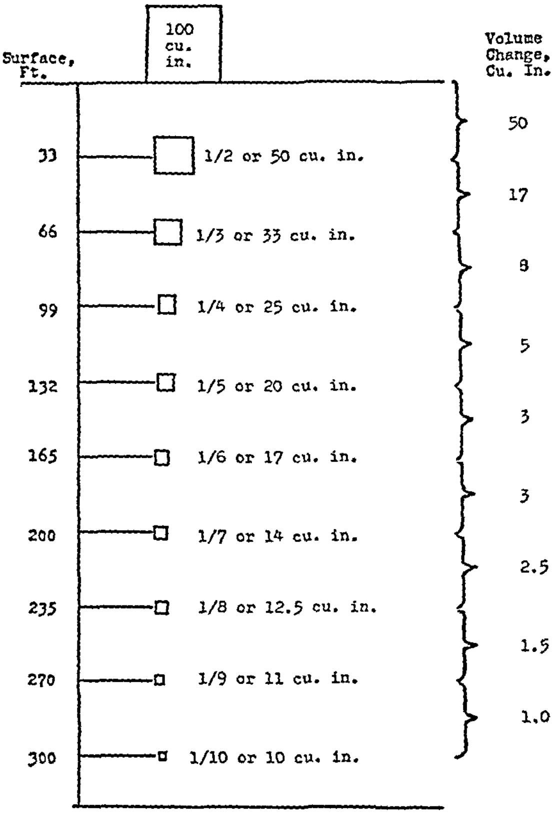
Diving diseases and accidents formerly were very uncommon and understandably unknown to most physicians except for a few who were specially trained to cope with them in the United States Naval service. With the ever-increasing hordes of skin divers each year, diving accidents are becoming more commonplace. In California from January, 1953, through April, 1955, there has been an average of about one fatality per month. There were, of course, many nonfatal accidents, and there is obviously a need of improved safety programs for the diving public. Most urgent also is the need for the medical profession to be brought up-to-date in this field. A great deal of progress has been made to date by lay organizations to educate the public regarding the all-important matter of diving safety. Several local groups are active in this program of public education and safety. The Los Angeles County Department of Recreation has recently given a course in underwater recreation to a group of their instructors who, during the summer months, will be stationed at county beach and resort areas to further instruct divers in diving safety. The national Red Cross chapter in Long Beach, Calif., has a

---

Medical Consultant, Sparling School of Deep Sea Diving, Wilmington, Calif.

special department devoted to underwater safety. They have also inaugurated a uniform method of accident reporting. In addition to these two groups, there are publications that are beneficial to those who are interested.[1]

There are distinct types of sport divers. The first type, and the one to whom the term skin diver most usually refers, is the diver who wears a face mask and swim fins and relies on the limits of his ability to hold his breath to descend below the surface of the water. This group comprises the majority of divers. The SCUBA (self-contained underwater breathing apparatus) divers are those who rely on a breathing tank of compressed air or oxygen to supply them with a sufficient amount of oxygen while submerged. This allows deeper and more extensive underwater ventures. Divers of any classification are subject immediately to various diving diseases. There are basically two types of SCUBA units. The first is the "open-circuit" type. This unit is comprised of a tank of compressed air, face mask, and an automatic demand regulator. This type of regulator assures the diver a supply of air at the correct pressure regardless of depth. Waste air is exhaled outside the unit. The other type of breathing apparatus is a closed-circuit, or rebreathing, unit that features a breathing bag and contains 100% *oxygen as a breathing medium.* The breath is exhaled into a bag; oxygen is added and then rebreathed after it has been filtered through chemicals that absorb carbon dioxide and moisture. One other type of diving, which is still used but to a lesser degree than the above types, is done with homemade diving helmets and masks to which air is supplied by an air hose from surface air compressors. The limitations of the hose, the cumbersomeness of the helmet, and the necessity of having a topside tender to assure proper function of the compressor make this type of diving less popular than the "free" or self-contained units.



Boyle's law, as applied to pressure in skin diving.

PHYSICS AND PHYSIOLOGY OF DIVING

It is essential for physicians to become acquainted in a general way with the problems of a diver's environment. Toward this understanding it is important to review Boyle's law. This law states that if the temperature is constant, the volume of a gas varies inversely with the pressure. Hence, the greater the pressure, the smaller the gas volume. At sea level the air in our atmosphere exerts on the body a pressure of 14.7 lb. per square inch, or one atmosphere absolute. For each 33 ft. below the surface of the water the pressure is increased by an additional 14.7 lb. per square inch. So likewise by doubling the pressure from surface to a depth of 33 ft., the volume of air at a depth of 33 ft. would occupy half the volume formerly occupied at the surface. At a depth of 66 ft. the pressure would be three atmospheres absolute (43.1 lb. per square inch), with the gas at that level reduced to one-third its original surface volume (see figure). Therefore at a depth of 300 ft. below the surface the pressure would be 10 atmospheres (147 lb. per square inch), with a tenth of former surface volume of gas. An important factor to recognize at this point is that at shallow depths the changes in gas volume are greater than at deeper depths. For example, going from the surface to 33 ft., a given volume of gas would be reduced 50%. A compressed gas then starting at 33 ft. doubles its volume on returning to the surface. At deeper depths, for example, going from a depth of 270 to 300 ft. there is an increase of one atmosphere (14.7 lb. per square inch) of pressure but a change in gas volume of approximately 1%. Thus the large fluctuation in gas volume near the surface is of importance in limiting a diver's compressed air supply, in equalizing pressure on eardrums and sinuses, and in recognizing and preventing air embolism.

The law of partial pressures states that the pressure of a gas mixture is equal to the sum total of the partial pressures of all the gases contained in the mixture. Also within a mixture of gases, each gas exerts a pressure (partial pressure) independent of all other gases in the mixture. In our surface atmosphere the partial pressures of nitrogen and oxygen are of greatest importance. Under the increase of pressure, carbon dioxide poisoning, carbon monoxide poisoning, oxygen poisoning, and nitrogen narcosis all appear to be related to the partial pressure of the particular gas rather than the total pressure of the air at a specific depth. The total volume of a gas that can be dissolved in a fluid is directly proportional to the absolute pressure. This factor is of importance relative to nitrogen absorption by the body during a descent into the water and the release of the gas again by the body when surfacing. If sufficient nitrogen dissolves in tissues, then on rapid ascent the gas evolves from the tissues faster than the blood stream can carry it away, bubbles can form to block capillary blood flow, producing symptoms of anoxia to the tissue supplied by the capillaries. This bubble formation is the etiological factor in caisson disease or "the bends."

[1] Diving with Self-Contained Breathing Apparatus, prepared by E. H. Lamphier and J. V. Dwyer Jr., Special Report Series 1954, Washington, D. C., Experimental Diving Unit, U. S. Naval Gun Factory, 1954. Cross, E. R.: Underwater Safety, Wilmington, Calif., Diving Research Publishing Company, 1954.

Temperature exerts its effect on the body in the water. Ordinarily body cooling takes place by convection and evaporation. Underwater almost all heat transfer is due to conduction from the skin to the water. Cold water can produce a marked drop in body temperature unless some type of insulating suit is worn. Lower water temperatures increase the body metabolism, resulting in a more rapid use of the diver's air supply. Water density, tides, currents, and poor visibility are also factors to be reckoned with in the realm of the diver.

A more specific review of the gases in our environment should be made, since it is the effect that the above laws of physics has on these gases that makes the diver's world so different from his normal habitat. Oxygen occurs in a free state in the atmosphere, of which it forms about 20% by volume. At rest at atmospheric pressure, approximately one-fifth of the oxygen in each breath is absorbed by the body. Violent exercise may increase the amount of oxygen required 10 times over that needed at rest. Applying our gas laws to the diver's oxygen supply, it is seen that if he uses a tank of compressed air, which would supply him with enough oxygen to breathe for an hour on the surface, at a depth of 33 ft. of water the volume of the gas available in the compressed air tank would be one-half; hence it follows that he will have one-half (30 minutes) the air supply at this depth, all other factors remaining constant. If the diver descends to 66 ft., the volume of gas available will be a third that at the surface and would supply the diver with 20 minutes of breathing. Vigorous exercise or cold water temperatures may also further limit the compressed air supply. It is important to plan a dive ahead of time so as not to stay too long at a particular depth and exceed the available oxygen supply. Oxygen lack deadens the faculties, and loss of consciousness may occur quickly before a person realizes what has happened.

Nitrogen, by way of review, comprises about 79% of our air supply. At atmospheric pressure nitrogen has no effect on the body except to serve as a diluent for oxygen. Under pressure nitrogen has two important effects on the body. A narcotizing effect occurs at about four atmospheres absolute (approximately 100 ft.). The effect is similar to the euphoria occurring with alcoholic intoxication. At depths of 300 ft. (10 atmospheres) this is to such a degree as to make attempts to accomplish work impractical. Nitrogen, as the pressures of increasing depths are reached, continues to dissolve in the body tissues. Nitrogen dissolves in fatty tissues to a marked degree. The ratio of fat to water solubility is approximately 5:1. Hence, it is easy to see that with an excess of fat in the body there is an increased ability for the body to retain nitrogen and also an increased tendency for an obese individual to be more susceptible to caisson disease.

Another gas of our normal environment is carbon dioxide, which is known as a natural product of respiration. It comprises about 0.04% of the normal air. Concentrated by low temperatures, increased pressures, and inadequate ventilation, carbon dioxide builds up. When the amount in inspired air reaches 5%, panting occurs; 8% produces increased respiratory distress; 10% produces loss of consciousness. Warning signs of excess carbon dioxide are panting, fatigue, headache, dizziness, and nausea. Symptoms of carbon dioxide poisoning do not occur in "open-circuit" breathing apparatus described above because exhaled air is blown outside the diver's mask. With a homemade helmet or mask carbon dioxide increases can quickly occur if insufficient air is allowed to circulate through the helmet or mask. The above laws of physics and facts concerning the gases of the diver's atmosphere are presented to briefly show the physician's reasons for the importance of safety in diving and the importance of good health for the participants.

PHYSICAL REQUIREMENTS FOR DIVING SAFETY AND COMMON ACCIDENTS

On a health examination the following points are of great importance, and here is where the family physician can serve best to prevent accidents. Perfect health is mandatory. The ideal type of individual is young, slender, and composed and with good vision. Obesity is a definite hazard, as fat tends to retain nitrogen. Since most obese individuals are usually out of condition, they are more prone to exhaustion. Exhaustion is one of the most common hazards to a diver. If treading through water is compared to continuously walking up stairs, it is easy to see that an individual must be in good condition to participate for any period of time. It becomes obvious that any type of chronic illness, such as arthritis, chronic otitis media or sinusitis, heart disease, asthma, syphilis, and chronic gastric intestinal disturbances, is apt to prove disastrous to a diver. Any nervous tendencies in an individual should prompt a physician to discourage him from diving. Nervousness and panic accelerate one's metabolism and prevent clear thinking in situations where cool-headed thinking would otherwise prevent an unnecessary accident. Since most divers dive in teams, the frightened, nervous, or panicky individual can jeopardize the lives of others who may find it necessary to go to his assistance. Incidentally team diving is encouraged, and many times a diving buddy has been the one to assist an exhausted or frightened diver to the surface and safety. A prospective diver should, of course, know how to swim and be at home in the water.

Clean living habits, adequate rest, and plain simple diets are to be encouraged. The effects of cigarettes and alcohol are well known, and the obvious circulatory retardation imposed by them can be dangerous to divers. Individuals who tend to have excess intestinal gas or are prone to constipation should also be discouraged from diving. Head colds are particularly detrimental in diving and may decrease pressure toleration on sinuses and ears. If eustachian tubes are sufficiently edematous so
as to prevent equalization of pressure on the eard
rupture of the drums can promptly ensue wit
10 lb. of pressure. Under pressure an ind
force infected mucus into the mi
lungs, with resulting infection
tion.

CAISSON DISEASE

Caisson disease can occur when a sufficient amount of nitrogen has dissolved in the body tissues and is then followed by a rapid release of pressure. Bubbles form first in the blood stream in areas of poor circulation such as joints, bones, or fat. Mechanically these bubbles occlude a blood vessel and cause tissue anoxia beyond the point of occlusion by the bubbles. Mild symptoms consist of skin itching and pain in joints, tendons, or muscles. Symptoms occur from a few minutes after surfacing up to as long as 15 hours after surfacing. Sometimes the onset of symptoms begins before the diver reaches the surface. Serious symptoms are those of dizziness, vomiting, visual disturbances, and paralysis. Loss of consciousness and death can follow in serious cases. Treatment consists of immediate measures to combat shock; give sedation for pain and to get the patient to a recompression chamber as promptly as possible (see table). Practically every coastal area is within an hour or two of a recompression chamber. Contacting the U. S. Coast Guard will get any physician in touch with the nearest available treatment facilities. Recognizing caisson disease, giving any necessary emergency treatment, and getting the patient on the way to the nearest recompression chamber are the ways we can best serve those stricken with this disease.

Differential Diagnosis for Diving Diseases

Disease	Etiology	Symptoms and Signs	Treatment
Mild caisson disease	Diving in excess of 40 ft. for prolonged periods	1. Onset usually few minutes to 15 hr. after surfacing 2. Pain in joints (knee, elbow, and spine) 3. May have itching or mottling of skin 4. No tenderness, swelling of joints as in sprain	1. Sedation for pain 2. Recompression in chamber as promptly as possible ....
Severe caisson disease	Same as above	1. Onset may occur before reaching surface and up to 15 hr. after surfacing 2. Joint pain as above 3. Vertigo, vomiting, visual disturbances, paralysis, and coma	1. Sedation for pain 2. Emergency treatment for shock 3. Prompt recompression
Air embolism	Diving in excess of 6 ft.; no tissue saturation necessary	1. Symptoms usually occur within few minutes after surfacing 2. May expire before reaching surface 3. Symptoms of severe caisson disease above 4. May show spontaneous pneumothorax	1. Sedation and treatment for shock 2. Artificial respiration and oxygen inhalation 3. Recompression as quickly as possible ....
Asphyxia (carbon dioxide poisoning or drowning)	Accumulation of carbon dioxide, by loss of breathing apparatus, exceeding air supply	1. Panting, fatigue, vertigo, and nausea 2. Convulsions, coma, and apnea 3. Cyanosis	1. Prompt surfacing 2. Artificial respiration 3. Oxygen or carbogen inhalation 4. Treatment for shock
Carbon monoxide poisoning	This gas is a contaminant of the compressed air supply	1. Severe headache 2. May develop fatigue, vertigo, nausea, general uneasiness, coma, and apnea 3. Cherry-red skin, nail beds, and mucosa	1. Surface and remove breathing apparatus 2. Artificial respiration 3. Oxygen inhalation 4. Shock measures
Oxygen poisoning	Breathing pure oxygen under pressure	1. Symptoms of bronchial irritation, vertigo, emotional disturbances, and muscle twitchings 2. Severe convulsions may occur	1. Prompt reduction of pressure 2. Sedation and antispasmodics if convulsions persist

Caisson disease rarely occurs at depths less than 40 ft. Divers using a single tank of compressed air are so limited as to time at depths in excess of 40 ft. that they are not prone to develop the "bends." The difficulty, however, is that ever-increasing numbers of divers are using multiple tanks of compressed air to prolong the time they can stay at deeper depths. To add further to this danger Comp[illegible] divers will have a total of four to six tanks of air with them on a particular trip. It is not unusual for them to make two or three dives during a single day without allowing time for decompression during any of their ascents to the surface. It should be noted at this point that the danger of several dives during a single day lies in the fact that a subclinical amount of gas may remain dissolved in the tissues for several hours after an ascent from a single dive. If a diver makes another dive before the gas dissolved in his body from the first dive is completely eliminated, he retains this dissolved gas (nitrogen) and adds to it on the second and third dives. Thus even though a single dive was not of sufficient duration to allow enough tissue saturation to produce the "bends" on surfacing, the succeeding additions of gas dissolved in the tissues can add enough nitrogen for bubble formation. This is particularly apt to be facilitated by obesity, overfatigue, or diving in extremely cold water.

Actual instructions in treatment in the recompression chamber is purposely omitted at this time, but it is hoped that more doctors will become interested enough in the future to warrant a paper devoted primarily to this phase of caisson disease.

OTHER HAZARDS

Air Embolism.—Air embolism occurs when a diver using an underwater breathing apparatus ascends toward the surface holding his breath. As he ascends, the compressed air in his lungs must expand. The expanding air then may rupture alveoli and blood vessels and allow air bubbles to flow rapidly into the pulmonary circulatory system. The bubbles can quickly collect in the left chambers of the heart, occluding the circulation to the great vessels with sudden asphyxia and death. Symptoms can occur from depths as shallow as 7 ft. The symptoms usually occur promptly after surfacing, almost always within 10 to 15 minutes but may occur before reaching the surface. They are symptoms of a serious case of caisson disease. Spontaneous pneumothorax may also occur. Emergency treatment consists of absolute rest with head down, artificial respiration, carbogen or pure oxygen inhalation, general treatment for shock, and recompression as promptly as possible.

Oxygen Poisoning.—Oxygen poisoning is a proved condition that occurs in some individuals when pure oxygen is breathed under pressure. As mentioned above, there are some self-contained units that use oxygen and a rebreathing closed-circuit system. Some people under pressure, who tolerate oxygen poorly, will develop toxic symptoms that can occur in depths as shallow as 33 ft. Symptoms are those of nausea, bronchial irritation, dizziness, emotional disturbances, muscle twitching, and convulsions. The symptoms can become more severe with increasing pressures. The treatment consists simply of reducing the pressure (surfacing) generally with prompt subsiding of symptoms. Convulsions can continue for several hours after surfacing. Use of pure oxygen as a diver's air supply is dangerous and should be discouraged.

Carbon Monoxide Poisoning. — Carbon monoxide poisoning can occur when a diver's air supply becomes contaminated with exhaust fumes. The source of contamination occurs when gasoline-driven compressors, used by manufacturers, are improperly vented. The exhaust fumes are included with the compressed air. Thus a diver inhales increased concentrations of carbon monoxide as he descends below the surface. The ratio of affinity of carbon monoxide and oxygen for hemoglobin is approximately 300.1. Under the increased pressures and higher concentrations of carbon monoxide typical symptoms of carbon monoxide poisoning occur. These are severe headache, fatigability, dizziness, faintness, general uneasiness, and loss of consciousness. As contrasted to the cyanosis of the asphyxiated individual, the unconscious victim of carbon monoxide poisoning shows a cherry-red appearance of the skin, mucous membranes, and nailbeds. Emergency treatment consists of surfacing, removing the contaminated source of air, administering artificial respiration, oxygen inhalation, and the usual measures for combating shock.

Psychological Hazards.—Psychological hazards are important among the medical hazards of shallow water SCUBA diving. An individual who is afraid of the water, perhaps a poor swimmer, and is alarmed by the experience of underwater diving is not likely to be calm or resourceful in event of an emergency. A good diver is neither overfearful nor audacious, but careful, foresighted, and calm in the face of difficulties, including panic among others. Unstable individuals should be discouraged from participating in SCUBA diving.

SUMMARY

Skin diving with use of self-contained underwater breathing apparatus is increasing as a popular sport. A public safety program is felt to be mandatory. Through a study of physics and physiology of diving, health qualifications for divers, and diving accidents and diseases, physicians will play an important role in the field of diving safety.

COMPLICATIONS FOLLOWING SURGERY FOR BENIGN ANORECTAL LESIONS

Raymond E. Anderson, M.D., Guy V. Pontius, M.D.
and
Leon J. Witkowski, M.D., Chicago

In spite of the fact that a certain degree of standardization of the surgical treatment of benign anorectal disease has evolved during the past decade, postoperative complications still occur too frequently. These are not due to neglect of the underlying technical principles of this type of surgery but rather to a disregard of the refinements in technique and attention to details in the surgical procedure and during the postoperative period. Although there may be minor variations in methods in various surgical centers, we do not believe that these are a significant factor in the incidence of postoperative complications. It is our opinion that adherence to the basic principles concerning the anatomy and physiology of the anorectal region will minimize or eliminate the high incidence of complications that unfortunately still occur. Other writers have reflected this opinion also, and, while it is undoubtedly true, it has tended to draw attention away from the cardinal necessity of developing clear-cut concepts relative to the early recognition and treatment of an abnormal postoperative state. No one can deny the importance of avoiding trouble by performing a technically perfect operation, and it is probably for this reason that little consideration has been given to the problem in the literature.

Postoperative complications are not only embarrassing to the surgeon but they are also annoying or even disabling to the patient. The fear and apprehension that surround dysfunction of the anorectal mechanism are especially acute in the postoperative period, and the prolonged convalescence that follows unrecognized or improperly treated complications places a distracting psychological burden on the person facing such an ordeal. Failure to correct decisively an adverse postoperative course in both its physical and its emotional components produces a patient who is not only despondent and filled

---

From the Fourth Surgical Service, St. Luke's Hospital, and the Department of Surgery, Northwestern University Medical School.

with misgivings but also skeptical and resentful at the outcome of his surgery. There is probably not another physiological function of the human body that is the object of more direct and indirect emotional attention than that of defecation. When it begins to appear in the patient's mind that some alteration in the normal experience of that act may result from the surgery that was explained to him as treatment of a benign condition, the pattern is created for certain anxiety and mistrust. With these thoughts in mind and assuming that occasional complications will occur even under the best of circumstances, we have endeavored in this discussion to draw from our own experience in the surgical treatment of approximately 5,000 cases of benign anorectal disease and to evaluate those factors that lead to complications in the postoperative period. We have accepted one or more of the following circumstances as being complications when normal recovery is retarded either by preventing the well-being of the patient or by altering restoration of anatomic or physiological function of the anorectum: (1) fecal impaction, (2) hemorrhage, (3) excessive pain, (4) infection, (5) outlet stenosis, (6) incontinence, (7) mucocutaneous fistula, (8) alteration of mucocutaneous junction, (9) pruritus, and (10) anal ulceration.

FECAL IMPACTION

Although the development of a hard mass of fecal material in the rectal ampulla is one of the most common and distressing complications that may occur in the postoperative period, it is often overlooked by the attending surgeon and members of the house staff. The presence of a bolus of stool in the lower rectum leads to pressure and congestion in the anal outlet, with a resulting increase in pain and spasm. There is no doubt that an accumulation of feces, mixed with blood and serum, offers an ideal medium for the growth of intestinal bacteria. This stagnating mass is excessively irritating to the healing surfaces of the mucosa and skin. Thus, the presence of congestion and edema, combined with infection, results in extreme discomfort to the patient as well as actual retardation of healing. It is a simple thing to determine whether or not an impaction is present by merely placing a finger into the rectum. One is easily misled, however, by the patient, suspected of having an impaction, who states that his intestine is emptying each morning. It must be emphasized that defecation may occur despite the presence of a hard shell of impacted feces above the anal outlet. Even a rectal digital examination is not foolproof and may be deceiving when there is a great deal of pain and spasm present. It is exceedingly difficult to explore the rectal ampulla thoroughly in these people, and because of this, a peripheral impaction may be overlooked. The administration of an opiate to obtain the cooperation of the patient may be essential to a proper examination if there is a possibility that an impaction is present.

All of our patients who suffer from anorectal disease are given a complete examination prior to surgery, which includes a proctosigmoidoscopic examination and, in most instances, an x-ray of the colon. Taking this x-ray within four or five days before the date set for surgery is unwise, because it requires at least this long to completely evacuate the barium from the colon. Any barium that remains in the large intestine at the time of operation adds to the risk of developing impaction. The simplest and least traumatic way to remove the inspissated stool is to use digital pressure to break up the mass, followed by liquid petrolatum (mineral oil) and saline enemas. Recently we have been using Phospho-Soda (aqueous solution of sodium biphosphate and sodium phosphate) in place of the saline solution, with satisfactory results. Sedatives are liberally administered before this procedure is carried out, and the procedure is repeated daily until the impaction is entirely removed. The use of hydrogen peroxide and other harsh or irritating substances should be strictly avoided. After removal of the impacted stool, the patient must be carefully observed for evidence of bleeding, for, regardless of how gently and cautiously the procedure is carried out, there is danger of opening recently ligated vessels. The application of an anesthetic ointment and hot, moist compresses has proved to be the best means of relieving the immediate pain that the patient experiences, and, in most instances, within a few hours there is complete relief of all discomfort.

HEMORRHAGE

Most important of the early postoperative complications following anorectal surgery is hemorrhage, for, unless its presence is recognized early and treated promptly, the welfare as well as the life of the patient is in jeopardy. Procrastination is inexcusable, and anything less than specific treatment directed at the exact source of the bleeding is unjustifiable. The unsound idea that all rectal bleeding will stop by placing a pack in or on the anal outlet and tightly strapping the buttocks together, or the false sense of security obtained by assuming that as the patient's systolic blood pressure drops the bleeding will subside, are without foundation and, if practiced on all patients who bleed postoperatively, will lead to disastrous results. While it is true that this method of treating rectal bleeding will control a certain number of the cases, it is advisable to search thoroughly for the source of the bleeding and then, having found its origin, carry out the proper therapy according to a specific rational plan.[1] The means by which bleeding may occur and the proper treatment for each type are summarized below.

Skin Bleeding.—The proper surgical treatment of most benign anorectal lesions calls for the removal of an adequate amount of skin in order to insure proper drainage and healing. This results in a denuded area that will frequently ooze and bleed from small capillary channels for some time postoperatively, a situation that may be quite alarming to both patient and surgeon at times. Occasionally the trauma of the passage of a stool, an enema tip, or the examining finger will dislodge a protecting clot or ligature on a vessel in the skin edge, resulting in fresh bleeding that fails to stop of its own accord. It is this type of external hemorrhage from small blood vessels that will respond well to the application of dry sterile absorbent gauze, with pressure and is not a very serious problem. When this manner of bleeding persists, however, *a thorough investigation of the patient's blood-clot-*

ting mechanism should be undertaken and immediate steps taken to correct any abnormalities that may be detected.

Bleeding from External Sphincter.—All components of the external anal sphincter are supplied with many small branches of the inferior hemorrhoidal artery. Whenever the sphincter is manipulated or incised during the course of an anorectal surgical procedure, arterial bleeding may therefore be incurred, and, if the bleeding is unrecognized at the time of surgery or activated in the postoperative period, a rapid and serious blood loss will result. If at any time there develops a continuous passage of bright red blood from the anal canal, immediate examination should be undertaken. This type of bleeding, we feel, warrants taking the patient to the operating room, where the proper facilities are available. A topical anesthetic such as dibucaine (Nupercaine), 1%, may be applied to the anal canal prior to the examination. If, however, one is unable to examine the area thoroughly with this simple analgesia and positively identify the source of the hemorrhage, the sphincter and perianal skin is infiltrated with a 1% procaine solution until proper relaxation is obtained. When the offending vessel is found, it is clamped and securely ligated with 00 absorbable surgical suture. No other packing or hemostatic agent is placed in the anal canal.

Internal Bleeding.—Although a moderate amount of bleeding may be expected after most surgical procedures in the anorectal region, the passage of large clots of dark blood, associated with other signs of blood loss, is obvious evidence that hemorrhage has taken place. The rich plexus of hemorrhoidal veins and arteries allow such bleeding to be a serious affair, and valuable time may be lost by indecision. If vascular shock is present or impending, whole blood should be given immediately and preparations for an exploration of the area made in the operating room. When the bleeding is vigorous and the administration of 500 cc. of whole blood does not alter the blood pressure or pulse, a rectal pack as described by Rolens[2] may be placed in the ampulla for temporary tamponade. When the patient is out of shock and able to tolerate an anesthetic, he is transported to the operating room, where a general anesthetic is given. The sphincter is dilated gently, and a search is made for the bleeding vessel. When found, it is suture-ligated with 0 absorbable surgical suture, and no other hemostatic agent is used. There are occasions, and these are fortunately quite uncommon, when the exact source of the hemorrhage is hidden in a subcutaneous or submucosal hematoma, thus making it impossible to ligate a particular vessel. In such an instance, a dumbbell pack may be inserted in the lower ampulla and anal outlet for hemostasis. This packing is left in place for 48 to 72 hours, depending on the severity of the bleeding, and is then cautiously removed after the patient is sedated. A low-residue diet is given to the patient for several days after its removal.

Postoperative bleeding is often an unforeseen mishap, but, by keeping in mind several practical surgical principles, its likelihood may be minimized a great deal. The ligation of hemorrhoidal veins cephalad enough to obliterate the main channel is essential, and the use of a running, locking suture over the hemorrhoidal bed, after the fibers of the external anal sphincter have been carefully dissected away from the overlying tissue, has proved to be the best method of insuring closure of the collateral vessels. Arteries are always individually clamped and ligated. Before any suture or ligature is cut, the strands are relaxed in order to insure that the knot, rather than the tension, has controlled the bleeding. The entire area is inspected at the completion of the operative procedure, and, except to control the external skin edge oozing, pressure packs are not relied upon to produce hemostasis.

EXCESSIVE POSTOPERATIVE PAIN

The etiology of excessive postoperative pain is often obscure and difficult to evaluate because of the frequent interrelationship of functional and true organic elements in its pathogenesis. Tolerance to pain will vary greatly among people, and factors such as fear, insecurity, apprehension, and fatigue may each contribute in some measure to lowering the individual's threshold to pain. We have been impressed with the number of times the psychosomatic manifestation of extreme postoperative pain has had its origin in the fear of malignant disease, and we have often utilized practical bedside psychotherapy with much success in patients who appeared to be suffering from severe and agonizing postsurgical distress. Cooperation and confidence on the part of the patient is often of much more value in the relief of pain than the administration of large doses of the opiates or the injection of the long-lasting anesthetics. There are, however, a number of organic reasons that may account for unusual pain postoperatively, and undoubtedly the majority of these are due to faulty technique at the time of surgery.[3] Clinical experience has verified the correlation between the amount of postoperative pain and the degree of trauma in the anal outlet that the operation requires. Nevertheless, this factor alone is not solely responsible for the development of unusual pain following anorectal surgery. An equally important evaluation would undoubtedly demonstrate the parallel relationship between the amount of distress and the errors in judgment as to that technical undertaking of the surgery. The more important of the factors that may lead to trouble are discussed below.

A factor such as failure to remove an adequate amount of skin distal to the mucocutaneous line results in the presence of edematous and congested tags of tissue that are rich in somatic nerve endings and that interfere with the proper drainage of the operative bed. Inflammation may rapidly develop under such circumstances and add to the pain experienced by the patient. Removal of an excessive amount of skin in the anal canal and outlet or in the perianal margin denudes the external anal sphincter and allows direct irritation of the very sensitive fibers of this muscle. Constriction occurs, and the vicious cycle of pain, spasm, and improper healing begins. Although under voluntary control, the external anal sphincter is one of the most excitable and responsive muscles in the body, and inflammatory or mechanical trauma to its fibers, in addition to being extremely painful, will cause violent and sustained contraction to occur. A high percentage of cases of severe postoperative pain have their origin in sutures and ligatures that are improperly placed about the anorectal area. The external anal sphincter must always be carefully dissected away from the overlying skin, and care must be taken to prevent piercing of the muscle by placing the surgical suture too deeply. Direct vision and palpation are probably the best methods of avoiding this pitfall, and the mass clamping of excessive tissue with bulky ligation can only lead to distress. Although it is not a widely advocated or accepted procedure, there are some surgeons who feel the introduction of an anal pack or plug is necessary for hemostasis after anorectal surgery. It has been our experience that such a procedure invariably results in considerable discomfort and actually does little to promote hemostasis if careful identification and ligation of bleeding vessels is carried out during the course of the operation. A small, soft rubber catheter, placed into the ampulla for 48 hours to allow the escape of gas and facilitate the introduction of a liquid petrolatum enema on the second postoperative day, is the only type of foreign body that we feel is justified. Infection and fecal impaction are common causes for pain, but, since they are discussed elsewhere in this paper, they need only be listed here.

[3] Elkins, R. F.: Pre- and Postoperative Care in Proctology, South. M. J. 46: 182-184 (Feb.) 1953.

From the observation of the above-mentioned factors, it becomes clear that there is certainly no panacea for the relief of postoperative pain, with the possible exception of administering massive doses of the opiates, during a time when some corrective healing will naturally occur. This, obviously, is not following the principles of sound surgical therapeutics, and it therefore becomes necessary, when one or more of the above-mentioned circumstances is found to be responsible for an excessive amount of pain, to direct one's attention and energy to its eradication. When examination of the area is carried out, it should be kept in mind that somatic innervation reaches only to the mucocutaneous line, and, with the exception of the feeling of fulness, distention, and congestion, severely painful sensations will not originate above this point. The source of the pain, therefore, is not difficult to determine and, when located, should receive active treatment until it no longer remains a focus of irritation.

We have found that for those persons in whom edematous, swollen perianal skin is the basis for discomfort, the use of warm, hypertonic saline packs or salt water sitz baths serves best to relieve the congestion. When the converse is true and excessive skin has been removed, with exposure of the external anal sphincter, liberal use of a 1 or 2% aqueous solution of merbromin (Mercurochrome), which is applied twice daily, acts as a soothing antiseptic that also stimulates rapid epithelization of the defect. Topical anesthetic agents may also be applied, but evidence of local irritation or maceration of the perianal skin should indicate their withdrawal. Infection in the anal outlet or along the suture lines is best handled by the same methods that are used for an infection anywhere else in the body, namely, the application of hot compresses, the administration of the antibiotics or chemotherapeutic agents, and the assurance of adequate drainage. It must be emphasized that a number of the orally administered antibiotics are notorious for the way in which they lead to the development of proctitis or perianal irritation, and, for this reason, it is probably less hazardous to give this type of medication by the parenteral route.

Sutures or ligatures that have penetrated into the sphincter muscle present a difficult problem, which is probably best handled by the local use of anesthetics and the administration of narcotics, until the time when the offending strand can be removed. Contrary to the opinion of some proctologists, we believe that frequent postoperative digital dilations of the anal canal that break up adhesions and prevent sealing of skin edges are helpful in assuring better healing, promoting more adequate drainage, and lessening spasm and irritability of the anal sphincter.[4] We have seen a number of patients in whom disabling postoperative pain has arisen from no other source than an extremely spastic muscle and who have responded dramatically to frequent anal dilations.

For those persons who do not respond to any of the above methods of treatment or in whom pain persists, despite inability to locate an exact source of the distress, either functional or organic, we have resorted, on occasion, to the injection of the so-called long-lasting anesthetic agents. Our enthusiasm for this form of therapy has never been great, for the untoward side-effects that may develop following their use are often more annoying than the condition for which they were utilized. Superficial necrosis, deep abscess formation, local itching and urticaria, and the possibility of systemic reaction are some of the reported and personally observed complications that occur. Nevertheless, the application of long-lasting anesthetic agents to the problem of excessive post-surgical pain is acceptable and often yields gratifying results when all other forms of therapy have failed.

INFECTION

The anal outlet and lower rectum, rich in vascular and lymphatic channels and surrounded by loose areolar tissue, are susceptible to infection in a variety of ways. It is remarkable indeed that in this area, serving as a passageway for the elimination of waste products, containing uncountable millions of bacteria from the intestinal and upper respiratory tract, violent infections are not more frequently encountered after surgical trauma. In all probability there is a certain degree of local tissue immunity that offers resistance to growth of pathogenic organisms, but it is unlikely that this factor alone can protect the patient from developing postoperative sepsis. More fundamentally important is the avoidance of infection by providing at the time of surgery adequate drainage of the traumatized and susceptible area, a principle understood and utilized by proctologists for a great number of years. By establishing free drainage, potentially virulent bacteria, together with their toxic products, blood, serum, and necrotic tissue, pass to the outside and thus are rendered harmless. Contamination is confined to the superficial layers, and involvement of the deeper structures by invading organisms is prevented.

It is logical, therefore, that the inability of the surgical area to drain properly, either because of the blockage of already developed drainage ways by congestion or edema about the anal outlet or because of failure of the surgeon to originally provide sufficiently wide radical incisions for the exit of bacteria, is the most common cause for postoperative infection about the anorectum. Other etiological factors include the inoculation of pathogenic organisms into the deeper tissue by the passage of sutures or improperly placed and buried ligatures; examination or manipulation in the postoperative period with dirty instruments or gloves; irritation, inflammation, and direct invasion of the area by unusually potent diarrheal-producing intestinal or respiratory bacteria; and cutaneous allergy to locally applied antiseptics, anesthetic agents, or foreign materials, followed by diffuse inflammation.

[4] Pontius, G. V.: Treatment of Fissure, Hemorrhoids and Fistula in Ano, S. Clin. North America 23:255-290 (Feb.) 1943.

Postoperative anorectal infections may be of several types. The manner in which the responsible organisms are introduced and the nature of the bacteria, of course, determine largely the way in which the infection manifests itself, although such factors as bacterial synergy, availability of culture mediums, and local environmental conditions may also be important. The most common offending organisms are Escherichia coli, Pseudomonas aeruginosa, Proteus vulgaris, and the micrococci and streptococci.[5] Mixed infection is more apt to occur than invasion by a single strain of micro-organisms. Anorectal infection has been classified and analyzed by a number of workers,[6] and it is not our intent at this time to reevaluate the various types of inflammatory processes that may occur in this region. From a surgical viewpoint, however, it is important to point out that the majority of postoperative infections begin either at the anal margin, at the posterior triangular space (Minors), or at the mucocutaneous line, when disruption of its junction results from faulty surgical approximation. The type of infection may range from a simple circumscribed tegumentary involvement to a diffuse, ascending cellulitis or massive ischiorectal or perianal abscess formation. The symptoms and signs of anorectal infection follow the same pattern as those that become apparent in response to an infectious process elsewhere in the body. Chills, fever, and malaise develop early and may be extreme. The latter manifestation, we feel, is quite important in anorectal sepsis, for it probably indicates hepatocellular dysfunction, resulting from the release of septic emboli and toxic products into the portal circulation. Local reaction leads to pain, burning, pruritus, and, quite frequently, tenesmus and dysuria.

Examination should be carried out only after sedatives have been liberally administered. Digital exploration may fail to locate the point of infection, and, if there is any question as to the exact nature of the process, the attending surgeon should not hesitate to insert an anoscope or proctoscope in order to determine the character of the lesion. Treatment consists in application of the principles used to combat infection wherever it may occur. Rest, assurance of a proper state of hydration, adequate vitamin intake (especially that of vitamin C), and the administration of the proper antibiotic or chemotherapeutic agent are vitally important. Local therapy is directed toward increasing the vascularity by the application of hot compresses and by the reestablishing of free drainage. When localized abscess formation is discovered, incision is necessary, whether the fluctuation is at the anal margin or above the mucocutaneous junction.

However insignificant the abscess may appear, it is best not to attempt surgical drainage unless proper equipment and lighting are available. These are usually found in the operating room or office primarily arranged to care for patients with rectal disease. Thiopental (Pentothal) sodium given intravenously and combined with 1% procaine solution injected locally has proved to be an excellent anesthetic to use when dealing with this problem, although one must use extreme caution to prevent the dissemination of the infection by introduction of the needle through diseased tissue into healthy tissue. Frequent postoperative digital dilations of the anal outlet are probably the best insurance against faulty drainage, and this procedure is one of the most satisfactory ways to reestablish drainage if infection develops. Rapidly healing skin edges that block exit pathways are spread open, mucocutaneous pockets or sinuses are uncovered, and granulating shelves of tissue are broken down. The intensity of the infection governs the frequency with which the procedure is carried out; if it is repeated every three to five days, however, drainage is assured, healing progresses properly, and the period of convalescence is shortened considerably.

OUTLET STENOSIS

An abnormally narrow opening of the anal canal after surgery for benign anorectal disease may be the result of either removal of an excessive amount of skin without allowing a bridge of epithelium to remain between segments so removed or postoperative infection or inflammation at or below the anorectal junction. In either condition, however, the pathogenesis of the process leading to the stenosis is identical and consists of the deposition of fibrous scar tissue, which replaces the normal tegumentary structures, thus drawing the anal outlet into a fixed and inelastic aperture. Although Bacon [5] has described fibrous trabeculations extending into the superficial fibers of the external anal sphincter, which probably help anchor the scar tissue to the underlying structure, the essential process does not involve the muscle bundle itself. The voluntary and involuntary activity of the sphincter remains intact, but, as a consequence of its being trapped by the core of scar tissue, its ability to dilate in response to the passage of a stool is prevented.

Inflammatory conditions or infection may, in addition to initiating slough and scarring, involve the pectineal fascia, and fibrosis of this structure will eventuate in contracture and compromise in the lumen of the anal canal. Whitney,[7] Abel,[8] and others have given excellent descriptions of this phenomenon and have done much to clarify the importance of the pecten layer. Pain is an important symptom of anal stenosis but is not as commonly experienced as one would suspect. Evidence of outlet obstruc-

tion, as manifested by the necessity to strain during defecation, tenesmus, the passage of ribbon-like stools, and the sensation of incompletely evacuating the large intestine, have been just as frequently encountered in our experience. Cathartics are used uniformly and are often the only means by which the patient can affect a bowel movement. Diagnosis is, in the majority of the cases, established by a careful digital examination of the anal canal, but, in those persons who have an extremely irritable external anal sphincter, it may be necessary to obtain anesthesia before an accurate evaluation of the degree of narrowing can be elicited. Fibrosis and scarring may involve the entire circumference of the anal outlet or only a segment of the wall may be involved. Certainly the most common level is at the mucocutaneous line.

As we have emphasized in some of the preceding paragraphs, we believe that frequent postoperative digital dilations of the anal outlet will prevent too rapid healing of the skin and junctional tissue, and, by thus allowing a certain degree of epithelization to occur, induration will be minimized. As elsewhere where scarring occurs, stretching and massaging aids in softening and relaxing the fibrous bands. In the event that contracture has already developed, it becomes necessary to allow sphincteric relaxation by incision of the binding ring of tissue producing the stenosis. When the stricture involves the lower anal canal below the pectineal line, the best results are obtained by producing several radial incisions, deep enough to completely sever the fibrous ring but never so radical as to involve the underlying fibers of the sphincter ani. No attempt should be made to dissect away a portion of the scar, nor should undermining or removal of wedge-like masses of tissue be undertaken, for, in so doing, the increased trauma leads only to increased hemorrhage and further fibrosis. The incisions should originate well above the zone of the scar and be continued in a caudal and peripheral direction, far enough to insure proper drainage. The number of incisions will depend, of course, upon the degree of narrowing, but sufficient relaxation to allow the introduction of both the forefinger and middle finger to the distal interphalangeal joint should be procured as a safeguard against future contracture. After this procedure, digital dilations are given twice weekly until healing is complete and no further evidence of progressive constriction is present. This may take as long as 8 to 10 weeks postoperatively, and, even at the end of that time, the anal orifice may remain at less than optimum caliber. If the patient is free of pain and has established a fairly normal pattern of bowel habit, it is best for the doctor not to let his enthusiasm provoke him into additional attempts to repair the narrowed outlet, for the risk of increasing the deposition of scar tissue far outweighs the chances of improving the anatomic and functional result.

The dense induration of the pectineal fascia of the anal canal, which frequently develops as an aftermath of infection or trauma to this area after surgery, narrows the outlet in a somewhat different fashion. As the process develops, the subcutaneous tissue beneath the pectineal line draws the anal canal into a fixed diameter, even though there is adequate elastic skin distal to this level. Divulsion of the anal canal as a remedy for this condition is an ill-advised procedure, for the submucosal hemorrhage invariably produced by this maneuver tends only to augment the fibrosis already present, and little or nothing is gained. Incision of the pectineal band in the posterior midline gives immediate relaxation to the anal canal, and normal sphincter tone may then be relied upon to maintain proper anal function. In those people who suffer from excessive irritability of the sphincter mechanism, a posterior sphincterotomy may be carried out at the same time the pectineal fascia is incised. Frequent dilations after this procedure insure proper healing and adequate drainage.

INCONTINENCE

With the possible exception of cancerphobia, the fear of being unable to control the passage of gas and fecal material from the rectum is uppermost in the minds of all persons facing anorectal surgery. There is not only a natural apprehension to submit oneself to a surgical procedure upon an area the proper function of which is necessary for unqualified social acceptance, but the number of rumors, half-truths, and sordid tales of "loss of control" following surgery of the anorectum are quite numerous among those who suffer from disease of this area. Unfortunately, these stories too often contain more than a small degree of fact, a situation that offers support to the reluctance and aversion of those people afflicted with anorectal disorders to seek surgical remedy for their distress. Certainly, one cannot ridicule the indisposition of those who delay undergoing treatment when they harbor the anticipation that the price they may have to pay for relief is the terrible plight of finding themselves unable to regulate the exit of material from the large intestine.

Anal incontinence is most commonly the consequence of laceration of the sphincter muscles at the time of surgery, with faulty healing of the incised or divulsed fibers. The degree of dysfunction is for the most part dependent upon the proportion of the muscle so transected, although this factor alone does not always account for the relative extent of seepage or soiling. Comparatively minor injuries may heal with enough disruption of the anal canal to cause embarrassing symptoms, yet deeper and more extensive trauma, which mends in a kindlier manner with a more satisfactory approximation of the loose muscle bundles, will occasionally result only in a predicament of equal severity. The degree of muscle continuity, however, remains as the most important factor in preserving anal continence. Various gradations of dysfunction, ranging from some weakness in voluntary activity when the subcutaneous portion of the external sphincter is divided to complete inability in preventing the escape of the intestinal contents when all components of the muscle are involved, may be encountered.[9]

Often overlooked by the proctologic surgeon is the danger that postoperative incontinence may be initiated by excessive stretching of the sphincter ani during the operative procedure. It is interesting to note that the anal sphincter is one of the last muscles of the body to become relaxed under the influence of a general anesthetic. By excessive dilation before complete relaxation is obtained, the hasty or unwary operator may so exhaust the muscle fibers that their normal tonicity is decreased considerably and the voluntary influence on anal function is rendered ineffectual. Varying degrees of incontinence may also follow mechanical distortion of the anal canal, quite independent of muscle injury, as a consequence of faulty approximation of the mucocutaneous junction, development of mucocutaneous fistula, or the presence of scarring and stenosis of the outlet. Although in the strictest sense these conditions do not alter the ability of the sphincters to close the terminal portion of the intestine, they do represent circumstances that allow uncontrollable leakage and discharge, much against the patient's will. The problem can be dispatched, however, and normal function reestablished when the basic disturbance is corrected. When one considers the anatomic features of the anal sphincter mechanism, it becomes evident that, when muscle bundles have been severed and the ends have retracted, the anal outlet will be lost to voluntary influence, and, regardless of how the area between the parted fibers becomes replaced, fecal material and gas will escape freely. Surgical reapproximation of the muscle ends or, at least, re-creation of peripheral continuity of the sphincteric elements, is therefore absolutely essential in order to provide the distorted tissue with the ability to function normally as a constricting regulator for the passage of intestinal contents.

---

[9] Blaisdell, P. C.: Plastic Repair of the Incontinent Sphincter Ani, Am. J. Surg. 79: 174-183 (Jan.) 1950. Fansler, W. A.: The Repair of Anorectal Incontinence Following Operation for Fistula, South. M. J. 45: 229-232 (March) 1952.

The exact manner in which surgical correction of the anal distortion is accomplished will depend upon the nature and severity of the decompensation. Although a tedious and painstaking undertaking, the careful dissection of the frayed fibers from the scar tissue mass that renders them useless and a direct end-to-end approximation of viable muscle probably offers the greatest chance for restoration of sphincteric function. Overcorrection of the defect should be the objective of the operator, yet extreme caution must be exercised lest an excessive amount of tissue be removed, a natural temptation and often an unavoidable hazard. Mattress sutures of absorbable surgical suture serve well in this type of repair. Some workers have advocated the use of imbrication or "reefing" of the scarred or everted segment of the anal wall, especially in those cases in which the hiatus type of distortion is present, with a funnel-like deformity of the anal margin and prolapse of the mucosa. This procedure has special merit in those cases of long-standing incontinence, or when a considerable amount of muscle tissue has been lost, either through previous attempts at repair or through infection with slough—cases in which the risk of further loss of available functional muscle is appreciable. The utilization of fascial strips, wire sutures, and muscle transplants to support the anal outlet have all been attempted, and there is no doubt that each of these techniques has clinical applicability in certain cases. Plastic repair of the severed sphincter ani is often a disheartening problem, taxing both the skill and the patience of the surgeon, and yet a problem in which fastidious attention to even the most minor detail will yield satisfying results.

The people in whom a postoperative atonic sphincter mechanism leads to an annoying leakage of rectal contents, resulting in soiling and perianal irritation, in the absence of disease of the nervous system, respond well to sphincteric exercise. The patients are instructed to voluntarily contract the anal musculature 50 to 100 times every four to six hours during the day. It is gratifying to observe that the most skeptical recipients of this advice are not infrequently the ones in whom the optimum results are obtained.

MUCOCUTANEOUS FISTULA

It is oftentimes astonishing to observe the rapidity with which the tegumentary layers of the anal canal and perianal margin heal after surgical trauma. Epithelization of denuded areas begins almost immediately and progresses at a faster rate than does the repair of the underlying tissues. While this apparently natural law of regeneration would appear to hasten the period of recovery following surgery of the anorectum, its effect is quite the contrary, and, unless the surgeon utilizes some means to retard the speedy overgrowth of the cutaneous layers, a less than desirable result will frequently be obtained. The uniting of the skin level, prior to the granulation and proliferation of the subcutaneous structures, allows the development of a tunnel-like defect, an arrangement that lends itself readily to the formation of abscess tracts and fistulas. As the most cephalad border of the squamous and transitional epithelium is at the level of the mucocutaneous junction, it is at this point that the inner opening of such a sinus will be found. A mucocutaneous fistula, serving well as the nidus for bacterial growth and inflammation, must therefore be avoided if possible or promptly eliminated when discovered.

The best method of preventing the occurrence of mucocutaneous fistula is to repeatedly dilate the anal outlet and, in so doing, break down whatever epithelization has taken place during the period when the subcutaneous defect is being replaced by normal granulation tissue. In those persons who harbor some degree of proctitis prior to surgery and in whom longer than average drainage is essential in the postoperative period, we have sutured down the epithelial edges to the underlying tissues with fine absorbable surgical sutures, as a means of retarding its growth. Some men have advocated the use of chemical irritation of the raw surfaces in order to devitalize the cells, with the same objective in mind. In addition to the painful sequelae of this technique, however, there is the question of whether the application of irritating materials will stimulate rather than discourage the growth of new cells. When mucocutaneous fistula is discovered in the period before fibrosis and secure healing of the bridging skin have taken place, the tract can generally be spread open by firm pressure of the examining finger tip. If this method fails to completely expose the pathological channel, a topical or local anesthetic should be given and incision of the scar carried out. A small, curved blade, introduced into the upper opening and drawn out along the course of the fistula, is an excellent and accurate way to correct the problem. Persistent dilation until healing is completed in the desired fashion must be undertaken in all cases.

ALTERATION OF MUCOCUTANEOUS JUNCTION

The most important landmark in the anal canal is the mucocutaneous line, and preservation of its normal relationship to the anal outlet is a vital part of any procedure carried out in this portion of the intestine. Disruption of its margin following surgical trauma is the underlying mechanism responsible for the development of annoying complaints in the postoperative period. Probably the most frequently observed disturbance in anal function that can be traced to an alteration in the mucocutaneous relationship is the constant seepage of mucus and fecal contents of the lower rectum. This disheartening symptom occurs when an ectropion-like protrusion of secreting mucosa presents into the lower anal canal, the consequence of the surgeon's failure to approximate the dentate margin in a circumferential manner. The reverse of this may also develop, in which squamous or transitional epithelium is inadvertently brought up higher than the lower border of the mucous membrane, resulting in imbrication and retraction of the area so involved. Irregularities of this nature lead to imperfect closure of the anal lumen notwithstanding normal sphincteric function. The derangement of the adjacent crypts, papillae, and anal glands, because of the alteration in their anatomic position, invites the development of irritation and infection at the point of their distortion. Sloughing may occur and ulceration persists in spite of the most vigorous application of the usual supportive measures to combat bacterial invasion. Pain, spasm, and irritation complete the cycle of dysfunction and discomfort to the patient. Anoscopic examination will reveal the segment of everted or retracted mucosa, often surrounded by edema, erythema, and infection, and, in many cases, ulcerated patches of the anal wall may be demonstrated.

In the presence of severe, mixed hemorrhoids it is consistently difficult to place the mucous and squamous layers in proper and accurate apposition after the pathological tissue has been removed. At times an excessive amount of the protuberant clusters of internal hemorrhoids may be removed, thereby making it impossible to reattach the distal edge of the mucosa at the correct level. We have found that by slowly drawing out a gauze sponge that has been packed into the ampulla the degree of laxity of the internal hemorrhoidal mass can be better appreciated as the mucous membrane is prolapsed. Incision to the mucocutaneous line is always made by scalpel rather than by scissors, and hemostatic crushing clamps are never applied to the mucosa with tension at their edges. Incorporation of these measures into the technique of hemorrhoidectomy will reward the surgeon with a decided decrease in the number of complications at the mucocutaneous verge. Although conservative measures, involving the administration of the antibiotics, repeated digital dilations, and local application of cauterizing solutions, will occasionally be of benefit to the patient, the expeditious way to terminate the difficulty is to return the patient to the operating room and surgically correct the defect by excising the involved portion of the wall, freeing up the retracted or everted tissue, and reestablishing the continuity of the mucocutaneous line at the proper level. The postoperative management is then identical with that of any other simple anal plastic procedure.

PRURITUS

The problem of anal pruritus is a broad and intricate subject, and a voluminous amount of literature has accumulated concerning its etiology, pathology, and therapy. It is not our intention to review the many aspects of the disease, for that task has been completed by a number of writers, and their monographs need no improvement. It is pertinent to this discussion to consider, however, the occasional patient in whom the development of a pruritic state can be directly traced to the period following surgery for benign anorectal disease. When such a postoperative history can be definitely elicited, it offers every reason for encouragement to the physician, accustomed to treating this oftentimes disheartening problem, for it indicates in almost every case a definite etiology for the distress, devoid of the deep-seated emotional implications often found in the average patient with pruritus. The specific cause for the postoperative complaint is almost universally based upon either (1) a mechanical defect in the anal outlet; (2) the presence of a low-grade infection, persisting from the time of the operative procedure; (3) allergic phenomenon, initiated by the application or injection of antiseptic or anesthetic solutions; or (4) a combination of any of the foregoing.

The real difficulty in diagnosis arises as a consequence of the inflammatory dermatitis produced by constant scratching of the area and the continuous application of various ointments and creams to combat the torture of the itching perianal skin. The basic pathology is so often distorted by the secondary reaction that it cannot be determined until definite measures are taken to eradicate the maceration, edema, and weeping of the involved tissue. We have found that the simple regimen of sedatives, local application of nothing more than 0.5% aluminum subacetate solution three times daily, and clear instructions for the maintaining of a clean and dry anal outlet have satisfactorily controlled the irritation in almost every instance. In some of the more refractory cases we have resorted to the application of 1 or 2% hydrocortisone acetate, with excellent healing. A diligent search can then be undertaken for possible mechanical factors that may be responsible for aggravating the perianal itching, and proper measures can be carried out for their correction. The preceding paragraphs have enumerated and analyzed the various types of deformities that may result in a pruritus ani, and there is no further reason to evaluate them at this point. The infective and allergic states that lead to pruritus in the postoperative period are more often than not cleared up by conscientious adherence to the plan of treatment mentioned above. There is, occasionally, a need for a broader plan of therapy in those people who are suffering from a severe infection or abscess, involving the utilization of heat, antibiotics, and drainage. Restoration of normal anal anatomy and function will invariably relieve these patients of any further pruritus.

ANAL ULCERATION

An area of erosion in the anal canal after operative trauma is the manifestation of a localized focus of infection, resistant to the usual pattern of healing and epithelization. Ulcerated areas may be found in any position about the anal circumference but are much more common in the posterior midline. There is a definite and understandable reason for this, dependent upon the anatomic configuration of the external anal sphincter, the superficial component of which courses in a converging manner to the anococcygeal raphe deep to the subcutaneous circular fibers. The Y-shaped compartment thus delineated by this relationship is known as the posterior triangular space and is potentially an ideal location for invasion by infecting organisms from adjacent tissue. If the area is invaded, abscess formation or sloughing of the anal wall covering the recess, with persistence of a necrotic, irregular ulcer in the posterior midline, results. Lateral or anterior ulceration may also develop, but such an occurrence is relatively uncommon, and involvement in these quadrants is generally at the anorectal line as a consequence of surgical disruption of this structure. Suture material will frequently act as a foreign body focus for granuloma formation and secondary erosion.

Once again, the importance of proper removal of tissue and the providing of adequate pathways for the drainage of traumatized tissue about the anorectum must be emphasized at this point. For in almost every instance, and the importance of this concept could well tempt one to say "every instance," postoperative anorectal infection and ulceration originate and progress in tissue that has not been allowed to drain amply. Sufficient skin must always be removed in order to retard healing at this level and to prevent blockage of the drainage channels before the mucosa has united and potentially susceptible areas for infection remain. Repeated dilations are added insurance that such will not take place. If septic products are permitted to flow to the outside freely, there is little danger that the posterior triangular space or the mucocutaneous junction will become infected or ulcerate. Until the mechanical defects that have preceded the infection have been corrected or until drainage has been provided, the ulcerations will remain resistant to conservative therapy. It is logical and wise to resect the ulcer-bearing tissue at the time of the secondary procedure, for, in so doing, minimal scarring and contracture of the anal canal will ensue.

SUMMARY AND CONCLUSIONS

Complications following surgery for benign anorectal disease still occur too frequently. These not only may be annoying or even disabling but if allowed to persist may result in suspicion and mistrust in the mind of the patient. Some of the complications are observed in the early postoperative period; these are fecal impaction, bleeding from the operative site, infection, and excessive pain. The development of any one or more of these conditions is likely to delay or prevent proper healing, resulting in eventual anal function that is less than satisfactory. Other factors that complicate normal convalescence and recovery become evident later in the postoperative period; stenosis of the anal outlet, incontinence, fistula formation, or disruption of the mucocutaneous junction are the most important of the later sequela. Unless these can be avoided, surgical correction may be necessary.

There are several means by which complications may be reduced or eliminated. A closer attention to the restoration of the normal configuration of the anal outlet is essential. The provision of adequate pathways for drainage must never be overlooked. Frequent postoperative rectal digital examinations, in addition to assuring better healing by promoting drainage and preventing the formation of excessive scar tissue, have also proved to be the best means of recognizing trouble before it becomes a serious threat to the patient's welfare.

SURGICAL TREATMENT OF NONCALCULOUS BILIARY TRACT DISEASE

Daniel J. Preston, M.D., Wilmington, Del.

Unsatisfactory results of cholecystectomy for noncalculous cholecystitis are a frequent occurrence. Errors in diagnosis and incomplete surgical procedures are believed to be the cause of some of these failures. The purpose of this report is to discuss surgical methods for improving the results of treatment of noncalculous biliary tract disease. Cole[1] reports that 50% of gallbladders removed in the United States are noncalculous. Maingot[2] states that less than 25% of patients are free of symptoms after cholecystectomy for noncalculous gallbladder disease. Snodgrass[3] found 64% poor surgical results in this group. Bockus[4] says that colic occurs in one-third of patients with symptoms due to chronic cholecystitis without stones. Presuming these estimates are relatively accurate, one is impressed by the large number of patients who are chronically ill from noncalculous biliary tract disease or are disabled by pain after removal of their gallbladder.

A regrettable tendency to teach young surgeons that biliary tract operations should be reserved for patients who have evidence of gallstones does not take into account those individuals who have fixed noncalculous organic disease that cannot be corrected by conservative treatment. A laudable trend to exploration of the common bile duct at the time of cholecystectomy in an increasing percentage of cases is evident from current surgical literature. The chief purpose of common duct exploration in most reported series has been for detection and removal of stones. Such procedures may be followed by persistence of disabling postoperative symptoms when coexisting stenosis or fibrotic stricture at the sphincter of Oddi is overlooked or uncorrected. Obstructive disease of the cystic duct with associated infection and abnormal function of the gallbladder can be treated with good results by cholecystectomy and removal of the cystic duct, provided the disease process is limited to these structures. When obstructive disease of the common bile duct coexists with cholecystitis a good result cannot be anticipated from cholecystectomy alone.

Evidence of obstruction is found at operation most often at one or both of two key points in the biliary tract; these are the cystic duct and the terminal portion of the common duct (fig. 1). Biliary hypertension and stasis from impaired drainage due to hypertrophic stenosis or fibrotic stricture at the sphincter of Oddi is associated with degenerative changes in the pancreas because of the common channel for the pancreatic duct and common bile duct controlled by a single sphincter in most individuals. Reflux of pancreatic juice into the biliary tract and reflux of bile into the pancreatic duct can occur from obstruction at the sphincter of Oddi. Resulting chemical inflammatory reaction and recurrence or persistence of stenosis at the choledochoduodenal junction favors chronic ascending infection. Thus, a chronic progressive process characterized by cholangiohepatitis, cholecystitis, and chronic pancreatitis may eventuate. Adequate surgical treatment for these patients implies not only removal of the diseased gallbladder but also correction of obstructive disease at the sphincter of Oddi.

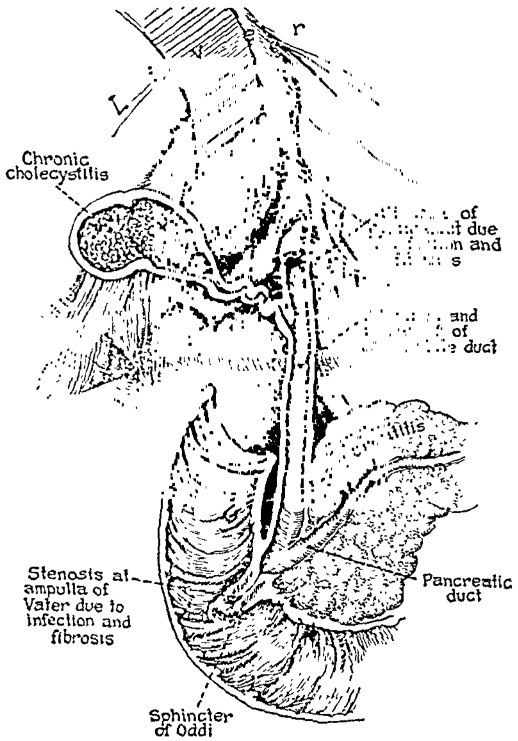

Fig. 1.—Chronic infection and fibrotic constriction causing impaired drainage due to stenosis at the cystic duct or the sphincter of Oddi.

INDICATIONS FOR OPERATION

The basis for selection of patients with noncalculous biliary tract disease for operation rests upon a concise history of typical recurring attacks of biliary colic and demonstration of reliable objective evidence of biliary tract disease. Preoperative study should attempt to determine the extent and severity of the disease process, which may be limited to the gallbladder and cystic duct or may include the common duct, liver, and pancreas. Estimation of impaired hepatic and pancreatic function is helpful in selecting the proper treatment before, during, and after operation. Evidence of cirrhosis or chronic fibrosing pancreatitis may alter an otherwise favorable prognosis. Promise of surgical cure is not justified if prolonged postoperative dietary and medical treatment for nonreversible fibrotic disease of the liver or pancreas may be required, even though one may hope to prevent progression of the disease process in these vital organs by surgical correction of chronic biliary hypertension.

A concise history of typical recurrent biliary colic and x-ray evidence of chronic cholecystitis are considered significant evidence of operable biliary tract disease. Bockus[4] believes that an absent or faint cholecystographic shadow is the most important objective finding in noncalculous cholecystitis. Delay in gallbladder emptying after stimulation by a fatty meal suggests functional or organic disease of the choledochoduodenal sphincter. Mallet-Guy[5] found cholecystography to be of no value for diagnosis of narrowing or fibrosis of the sphincter of Oddi. Sodium iodipamide (Cholografin), a new intravenously given contrast medium in 20% solution, is helpful in visualization of bile ducts. Abnormal dilatation of the common bile duct may be shown, though the cause is not usually apparent from films made by this method. X-ray studies are of no value in the presence of jaundice or when liver function is impaired sufficiently to cause 20% or more retention of sulfobromophthalein (Bromsulphalein) dye.

Typical attacks of biliary colic of short duration that occur soon after eating, show a pattern of increasing frequency and severity, are often associated with nausea and involuntary vomiting, and are not ameliorated by dietary management suggest operable disease of the pancreaticobiliary systems. A history of chronic dyspepsia and postprandial flatulence frequently precedes by months or years the onset of recurrent biliary colic. Progressive weight loss and vitamin deficiencies may be concomitant findings due to inadequate food intake and subnormal assimilation. Persistence or recurrence of biliary colic attacks after cholecystectomy suggests that removal of the gallbladder may have been an incomplete operation. Retained infected stump of cystic duct, overlooked stone in the common duct, chronic pancreatitis, unrecognized and uncorrected hypertrophic stenosis or fibrotic stricture at the sphincter of Oddi should be suspected as possible causes of pain after Cholecystectomy. Long-continued use of an indwelling common duct T-tube can cause chronic irritation with infection and fibrotic thickening of the duct, which may eventuate in late stricture formation after the T-tube has been removed.

Fever, chills, and clinical jaundice are uncommon after biliary colic due to noncalculous disease. Transient mild jaundice and low-grade fever may follow severe noncalculous colic due to cholangiohepatitis or extrinsic pressure on the distal portion of the common duct from enlargement of the head of the pancreas. Pancreatic enzyme levels in blood and urine are usually not elevated in patients with chronic pancreatitis. Tenderness high in the midepigastrium during and shortly after an attack of biliary colic suggests pancreatic involvement when it is associated with percussion tenderness at the left costovertebral angle. Muscle guarding without rigidity in the epigastrium is common during an attack. Except in acute cholecystitis, the gallbladder is not palpable or tender. A tender enlarged liver may be due to ascending infection and cholangiohepatitis. Angina pectoris, cardiac arrhythmia, and evidence of coronary atherosclerosis may coexist with biliary hypertension, especially in patients with the cholesterosis diathesis. Diabetes mellitus is a common associated finding in this group, though advanced fibrotic disease of the pancreas can develop without hyperglycemia or glycosuria. Obesity and coronary atherosclerosis do not contraindicate operation for organic biliary disease. Anginal attacks not induced by exertion may be relieved by interruption of deleterious autonomic viscerocardiac reflexes through surgical correction of biliary hypertension.

[5] Mallet-Guy, P.; Feroldi, J., and Micek, F.: Disease of the Sphincter of Oddi: Analysis of 70 Observations Collected from Dec. 7, 1945 to July 5, 1949, Lyon chir. 45: 181-199 (Feb.-March) 1950.

A typical attack of biliary colic that can be promptly relieved by inhalation of amyl nitrite or the sublingual application of a glyceryl trinitrate (nitroglycerin) tablet suggests that hypertrophic stenosis or spasm of the sphincter of Oddi may be preventing the normal flow of bile and pancreatic juice. Relief of pain by antispasmodics does not usually prevent or delay future similar attacks. In such individuals an injection of morphine may reproduce a typical attack of colic, presumably from spasm of Oddi's sphincter caused by morphine. Cholesterin crystals, pus cells, and pathogenic bacteria are demonstrable in fresh specimens of bile obtained by duodenal tube drainage when obstructive biliary tract disease exists. Twiss[6] believes the presence of colon-typhoid group and streptococcic organisms in duodenal bile is dependable evidence of biliary tract infection if there is free hydrochloric acid in the gastric juice. Chronic infection and back-pressure produce the visible changes of dilatation and thickening of the common duct found in these patients at operation.

The degree of functional impairment of the liver and pancreas in patients with biliary tract disease is difficult to determine by laboratory procedures. Results of chemical and enzyme tests show significant evidence of insufficiency and decompensation only in those patients who have advanced parenchymal damage. Intractable hypoprothrombinemia and sulfobromophthalein retention of 20% or more are indicative of serious degenerative change in the liver which may not be reversible after surgical correction of biliary tract obstruction. The normal liver has excellent regenerative ability.[7] Biliary obstruction and cirrhosis act to repress regeneration, though metabolism of protein and carbohydrate may remain normal for some time.

Patients with a concise history of frequent, recurring biliary colic and objective evidence of biliary tract disease often require operation for relief but should be given a trial of conservative treatment. Those in whom the symptoms and findings are not relieved by dietary management, antacids, antispasmodics, and anticholinergic medication should not be denied relief by surgical treatment.

DIFFERENTIAL DIAGNOSIS

Certain conditions that simulate biliary tract disease or coexist with it can usually be detected by a careful history, physical examination, and appropriate laboratory procedures. Peptic ulcer may mimic the symptoms of biliary tract disease and is usually revealed by barium x-ray studies. Posterior penetrating duodenal and gastric ulcers that involve the underlying pancreas can cause back pain and tenderness at the left costovertebral angle. They are not to be mistaken for similar symptoms and findings due to chronic pancreatitis. A preoperative diagnosis of early malignancy in the pancreas and stomach is difficult to establish by our present methods.

Small nonreducible epigastric hernia that may be overlooked on physical examination can be the cause of digestive symptoms suggesting gastric or biliary tract disease. In the absence of intra-abdominal disease, repair of the hernia will frequently relieve the digestive complaints. Symptoms of esophageal hiatus hernia may simulate symptoms of biliary tract disease. The hernia is best identified by barium x-ray studies. Back pain and tenderness due to a stone or infection in the left kidney is to be differentiated from symptoms due to chronic pancreatitis. The cause of back pain due to segmental neuralgia, protruded intervertebral disk, spinal arthritis, or metastatic malignancy of the vertebrae is established by history, neurological examination, and appropriate x-ray studies.

Substernal or precordial pain associated with attacks of biliary colic suggests coronary artery disease. Patients with cholesterosis diathesis who have chronic biliary tract disease are subject to attacks of myocardial ischemia from autonomic reflex coronary constriction. Angina pectoris, cardiac arrhythmia, coronary atherosclerosis, or myocardial infarction are detected by physical findings and electrocardiography. Anginal attacks not related to physical exertion suggest the pain may be due to autonomic reflex of biliary tract origin. Marked improvement in the cardiac status of these individuals can be obtained by surgical correction of organic biliary disease. Symptomatic hepatomegaly due to congestive heart failure is to be differentiated from the enlarged tender liver of cholangiohepatitis. Elective biliary tract operations should be postponed in the presence of recent myocardial infarction or untreated cardiac decompensation.

Duodenal diverticulum is infrequently the cause of symptoms. Coexisting biliary disease that may be the cause of complaints should not be overlooked. Duodenal diverticulum is considered the cause of symptoms if bleeding occurs or ulceration in the sac can be demonstrated by x-ray studies. Postoperative peritoneal adhesions do not usually cause pain unless they produce mechanical interference with normal gastrointestinal peristalsis. Pain in the upper abdomen ascribed to adhesions may be due to unrecognized biliary tract disease, peptic ulcer, or carcinoma. Abnormal gas distention of the colon can result from chronic constipation or partial obstruction by tumor.

Psychoneurosis and drug addiction may exist as the sole cause of symptoms or be associated with organic biliary disease. Frequent recurrence of biliary colic and inability to eat an adequate diet can lead to the development of a superimposed psychoneurosis or addiction to narcotics. Evaluation of such problems by a qualified psychiatrist may be helpful in determining the proper course of treatment. Rapid recovery from narcotic addiction and relief of psychoneurotic symptoms may follow surgical correction of biliary tract disease that is causing pain. Such patients should not be denied operation *when there is reliable objective evidence of biliary* tract disease. In our experience, a woman who had been given five electroshock treatments by a qualified psychiatrist without improvement in her psychoneurosis was apparently cured by operation that relieved her abdominal pain.

INDICATIONS FOR EXPLORATION OF COMMON BILE DUCT

Preoperative evidence of biliary tract disease may not be supported by operative findings. Conversely, more serious and extensive disease may be discovered at operation than was suspected. For these reasons only direct evidence found at operation should guide the surgeon in selection of the proper procedure in each case. The coexistence of two or more of the conditions discussed below revealed at operation are believed to warrant exploration of the common bile duct.

An opaque thickened common duct wall results from chronic infection and fibrosis. The wall of a normal common *duct is thin, translucent, and bluish in color*, resembling the color and resiliency of a normal gallbladder. Diameter of the common duct that is greater than 7 mm. results from obstructive disease distal to the dilated portion. Normal diameter of the choledochus is stated by Gray[8] to be equivalent to the diameter of a goose quill. Increased viscosity, dark color, turbidity, pus, or granular sediment in common duct bile is evidence of stasis and infection. Bile aspirated from the common duct via a needle introduced through the wall of the cystic duct is normally clear, of low viscosity, and has a light golden honey color.

Thickening, edema, or nodular fibrosis of the pancreas associated with a thickened or dilated common bile duct is presumptive evidence of obstructive lesion at the sphincter of Oddi. Only one of five clinical types of pancreatitis is due to reflux or back-pressure phenomenon as reported by Saint.[9] Chronic pancreatitis is probably not secondary to biliary tract disease when a normal common duct is present. Doubilet[10] states that 60% of pancreatitis is due to reflux of bile. The finding of cholesterolosis cholecystitis should alert the surgeon to the possibility of stenosis or dyssynergia of the sphincter of Oddi. A yellowish cholesterin deposit over the gallbladder mucosa is frequently associated with cholangiohepatitis and chronic pancreatitis. A thickened contracted gallbladder indicates long-standing infection and is frequently associated with disease disseminated to other parts of the hepatopancreatic system. It is more common in the older age group and should arouse suspicion of a stone in the common duct even though none is found in the gallbladder. Cole[11] reports that there is no jaundice in 45% of cases in which stones are found in the common duct. Jaundice, past or present, with a diseased gallbladder and common duct may be associated with a stone pocketed at the ampulla of Vater.

A dilated cystic duct suggests that sediment, sand, or stones previously in a diseased gallbladder may have passed downward into the common duct. A granular sediment or turbidity of gallbladder bile found in conjunction with a dilated cystic duct is presumptive evi*dence that the disease process also involves the common* duct. Objective evidence of stenosis or stricture at the distal end of the common duct is obtained by testing the patency of this portion with a 3 mm. malleable probe. When the common duct is found to be dilated and thickened, this procedure is done through an opening in the cystic duct, through incision made in the supraduodenal portion of the common duct, or by retrograde approach through incision in the second portion of the duodenum. Information obtained from manipulations through the cystic duct or supraduodenal portion of the common duct is less reliable and carries the risk of injury to the distal part of the duct. Passage of the probe under direct vision through the papilla of Vater by transduodenal retrograde approach is preferred.

SURGICAL TREATMENT

Preoperative evidence of noncalculous biliary tract disease is largely presumptive and supplies the indications for operation. Surgical exposure of the involved structures affords access to direct objective evidence of disease that becomes the basis for selecting the surgical procedure to be employed. Inspection and palpation of the abdominal viscera is done when the abdomen has been opened. Special attention is given to the stomach, duodenum, colon, pancreas, liver, and gallbladder for evidence of previously unrevealed tumor or ulcer in these structures. Removal of areolar and fatty tissue from the cystic duct and adjacent supraduodenal portion of the common bile duct by gentle dissection affords unobstructed view and access to these parts.

When indications for exploration of the common bile duct are found, the second portion of the duodenum is mobilized by Kocher's maneuver. A transverse incision is made through the antimesenteric wall of the duodenum at the level of the lower border of the head of the pancreas. The papilla of Vater is located by palpation with the index finger and by observing the point at which bile enters the duodenum when gentle pressure is applied to the common duct. Patency of the choledochoduodenal junction is tested with a 3 mm. probe gently introduced through the papilla. If the sphincter does not permit passage of this probe, incision is made upward through the papilla and sphincter of Oddi with the use of a small fistula probe for a guide (fig 2). Care is taken to continue the incision only to the upper limit of constriction. The common duct is then explored from below upward with forceps, scoops, and probes. Special attention is given to detection and removal of a possible stone pocketed in the ampullary portion of the common duct.

[9] Saint, E. G., and Weiden, S.: Studies on Pancreatitis, Brit. M. J. 2:1335-1340 (Dec. 19) 1953.

[10] Doubilet, H., and Mulholland, J. H.: Surgical Treatment of Recurrent Acute Pancreatitis by Endocholedochal Sphincterotomy, Surg., Gynec. & Obst. 86:295-306 (March) 1948.

[11] Cole, W. H.: Recent Trends in Gallbladder Surgery, J. A. M. A. 150:631-637 (Oct. 18) 1952.

After retrograde exploration of the common duct, ampulloduodenostomy is accomplished by suturing the edges of the ampulla of Vater to the edges of the duodenal mucosa to form a permanent enlarged opening at the choledochoduodenal junction. The new stoma is tested with 5 to 7 mm. probes and is considered satisfactory if all bleeding has been controlled by the sutures and no evidence of constriction is demonstrable. Continuous unimpaired postoperative internal drainage of bile and pancreatic juice into the duodenum without a T-tube drain is thus obtained. Recurrence of obstruction by late postoperative cicatricial stricture is prevented by the plastic anastomosis between ampulla of Vater and duodenum. Relief of biliary hypertension and improved drainage favors spontaneous subsidence of duct infection and permits recuperation of the damaged liver and pancreas after operation.

The duodenotomy incision is closed transversely in two layers with fine steel sutures. In 83 consecutive transduodenal procedures in which this method of closure was used, there has been no postoperative duodenal fistula from leakage at the suture line. The cystic duct is ligated at its junction with the common duct. Cystic duct and gallbladder are removed. Surgical elimination of sphincter action at the choledochoduodenal junction presumably results in nonfunction of a retained gallbladder as reported by Doubilet.[10] Cholecystectomy is believed advisable in all instances when ampulloduodenostomy is employed. Puestow [12] observes that animals that have a functioning gallbladder have a sphincter mechanism at the distal end of the duct and those that do not have a gallbladder do not have a sphincter.

Immediate results following ampulloduodenostomy are often excellent. Patients who had been unable to eat a normal diet and were disabled by frequent attacks of abdominal pain usually are able to eat a full diet and are free of pain when they leave the hospital. Sufficient time has not elapsed to permit evaluation of final postoperative results in patients who have had this operation. Those in whom clinical evidence of cirrhosis or chronic pancreatic disease is found may require postoperative medical and dietary management. The tabulation summarizes experience in a consecutive group of patients who had operations for biliary tract disease.

Operation	%
Transduodenal retrograde exploration of common duct	53.5
Cholecystectomy for stones	32.9
Ampulloduodenostomy	30.9
Sphincterotomy	14.1
Clinical evidence of chronic pancreatitis at operation	13.4
Stones removed from common duct	12.9
Ampulloduodenostomy for noncalculous disease	11.6
Cholecystectomy for noncalculous disease	9.0
Postcholecystectomy ampulloduodenostomy	4.5
Postsphincterotomy ampulloduodenostomy (1 case)	0.6

Much postcholecystectomy disability can be prevented in patients with noncalculous biliary tract disease if associated distal duct stenosis is looked for and corrected when the gallbladder is removed. Cattell [13] believes that fibrotic stricture at the sphincter of Oddi is a common cause of failure following cholecystectomy. Unwarranted or indiscriminate surgical exploration of the common bile duct for which no valid criteria are present is dangerous, meddlesome surgery and cannot be condoned on any pretext. The surgeon who fails to correct organic obstructive disease of the common duct revealed by proper evidence at the time of cholecystectomy is delinquent in his responsibility.

SUMMARY

Reduction in the number of unsatisfactory results following operations for noncalculous biliary tract disease is aided by proper selection of patients for operation and surgical correction of coexisting stenosis or stricture at the sphincter of Oddi when cholecystectomy is done. Transduodenal retrograde exploration of the common bile duct and ampulloduodenostomy are recommended when evidence of obstructive disease is found at the choledochoduodenal junction. This procedure relieves biliary hypertension and affords continuous unimpaired postoperative internal drainage of bile and pancreatic juice without a T-tube drain. Improved internal drainage of the biliary and pancreatic ducts permits spontaneous postoperative clearing of infection and favors recuperation of the damaged liver and pancreas. Unwarranted prolongation of ineffectual medical treatment or procrastination in obtaining surgical correction of fixed organic biliary tract disease shows disregard for a progressive process that may produce serious damage to the liver and pancreas.

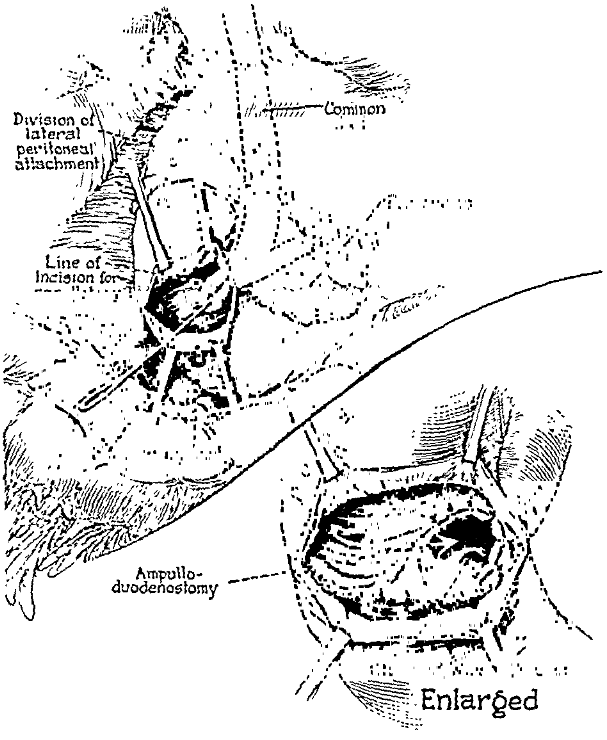

Fig. 2.—Fibrotic stricture of the sphincter of Oddi divided over a slender probe to permit retrograde exploration of the common bile duct. Enlarged diagram indicates plastic construction of a new stoma between the ampulla of Vater and the duodenum for continuous unimpaired internal drainage of bile and pancreatic juice after operation without a T-tube.

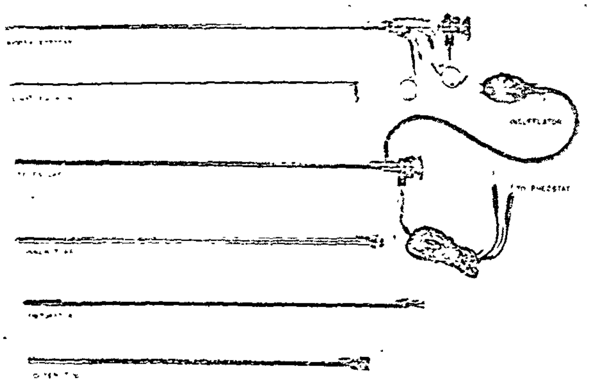
CLINICAL AND RADIOLOGICAL CORRELATIONS WITH OPTICAL ESOPHAGOSCOPY

Stephen J. Stempien, M.D., Beverly Hills, Calif., Angelo Dagradi, M.D., Long Beach, Calif.
Donald M. Sanders, M.D., Salem, Ore.
and
Rudolf Schindler, M.D., Los Angeles

In 1948, Schindler[1] reported the development of a new and safe optical esophagoscope. Two features of this instrument (see figure) offer a distinct advantage over conventional types. The rubber-tipped obturator enables the operator to introduce the instrument safely and easily, avoiding hypopharyngeal injury. The optical system has added a new dimension to the visual observation of esophageal anatomy, function, and pathology. Biopsy specimens are readily obtained. Only minor technical difficulties have been encountered; the most annoying of these is the occasional loosening of the light bulb in the optical system on some instruments, requiring adjustments during examinations. This difficulty has been overcome recently by the introduction of an outer telescopic system. It is the opinion of one of us (S. J. S.) that the length of 46 cm. of the standard instrument is too short and should be extended to 53 cm. There is only one limitation with this instrument. It cannot be used in lesions above the arch of the aorta; however, one of us (S. J. S.) was able to examine a lesion lying just above the arch. It must be mentioned that lesions in this vicinity are uncommon.



Optical esophagoscope.

Experience with this new instrument has shown that esophagoscopy need no longer be a hazardous procedure attended by the elaborate ritual of the operating room. Instead, it is now a relatively safe and easy office examination. This should inevitably result in a more extensive use of this important diagnostic method. In this paper we wish to report our clinical experience with this instrument during a period of four years from 1949 to 1952 at the Veterans' Administration Hospital in Long Beach, Calif.

RESULTS OF STUDY

Esophagoscopy was performed 197 times in 172 patients, of whom 166 were adequately studied and followed so that an accurate final diagnosis was established. These studies included: observation of the clinical course; repeat radiological and endoscopic examinations; endoscopic biopsy; surgical exploration; and autopsy. Our experience has shown that gastroscopy is often a valuable check upon roentgenography and esophagoscopy in cases of early varices and small hiatus hernia. A negative roentgenologic examination cannot be accepted as excluding disease of the esophagus. Of 56 patients in whom x-ray findings were negative, 13 were found to have esophageal pathology upon endoscopic examination: 4 had esophageal hiatus hernia; 3 esophagitis; 2 varices; and one each hiatus hernia with varices, carcinoma, telangiectasia, and extrinsic pressure. Hiatus hernia, esophagitis, and varices are the more frequent lesions that can be negative to x-ray examination. The one case of carcinoma was not disclosed on three separate series of upper gastrointestinal studies, which included fluoroscopic surveys directed at the esophagus. Subsequently, esophagoscopy and properly taken esophagrams demonstrated the lesion. The value of esophagoscopy in disclosing additional pathology that is not apparent from the radiological examination is shown by the finding of esophagitis in 10 cases, in 6 in addition to hiatus hernia and in 2 each in addition to benign constriction and carcinoma. Gastritis was found on esophagoscopy in five patients with hiatus hernia. This emphasizes the frequency of inflammatory complications in cases that are thought to be simple hiatus hernia, carcinoma, or cardiospasm.

Table 1 shows a fundamental disagreement in diagnosis between radiological and endoscopic examinations, in which the latter proved correct. In another 19 cases in which the x-ray findings were positive and esophagoscopic findings negative the latter proved correct; the x-ray diagnosis had been varices in 7 cases; hiatus hernia 4; stricture and filling defect 2 each; and varices or hiatus hernia, cardiospasm, hiatus hernia or ampulla, and irregularity in one each. Outstanding among the disagreements between these two methods is the frequency with which a small hiatus hernia is confused with varices and esophagitis confused with either carcinoma or benign cardiospasm. There was complete agreement between the radiological and the esophagoscopic examinations in a group of 36 patients, 20 of whom had hiatus hernia; 9 carcinoma; 2 each varices and benign stricture; and one each varices with hiatus hernia, cardiospasm, and extrinsic pressure.

On the other hand, table 2 demonstrates a group of nine patients in whom the radiological examination

[1] Schindler, R.: A Safe Diagnostic Optical Esophagoscope, J. A. M. A. 138: 885-887 (Nov. 20) 1948.

yielded more reliable information than the endoscopic method. In 10 additional cases a positive x-ray finding proved correct, although esophagoscopic findings were negative. This group included three patients each with diverticulum and hiatus hernia, two with varices, and one each with cardiospasm and stricture. Diverticula and certain instances of varices and small hiatus hernia may be difficult to demonstrate by esophagoscopy and, may be more easily demonstrated by x-ray.

There was a very small but important group of five patients in whom both methods failed to establish the correct diagnosis (table 3). The outstanding lesions that may give this difficulty are early varices and small hiatus hernias. In such instances, gastroscopy provides valuable diagnostic help. The instance in which a foreign body was mistaken for carcinoma was in a patient who swallowed a piece of meat that became adherent to the wall of the esophagus, then became covered by mucus, and appeared grossly like tumor.

TABLE 1.—*Cases of Diagnostic Disagreement Between Positive X-Ray and Esophagoscopic Findings in Which Esophagoscopic Diagnosis Proved Correct*

X-Ray Diagnosis	No.	Esophagoscopic Diagnosis	No.
Hiatus hernia?	2	Esophagitis with stricture	2
Varices	2	Hiatus hernia	2
Irregularity and ulcer	1	Esophagitis with diverticulum	1
Carcinoma	1	Benign stricture	1

COMMENT

Our experience with optical esophagoscopy clearly demonstrates that whenever disease of the esophagus and the cardia of the stomach is suspected, both the roentgenologic method and the endoscopic method should be used if the highest possible degree of accuracy is to be achieved. The radiological examination should precede esophagoscopy and always include properly taken esophagrams. A fluoroscopic survey of the esophagus in the course of routine upper gastrointestinal studies should never be accepted as an adequate examination of that organ. Furthermore, even an adequate x-ray examination that shows negative results should not be accepted as a sufficient diagnostic study for final exclusion of disease of the esophagus or cardia. If the signs and symptoms point to involvement of this region, an esophagoscopic examination is mandatory.

It is important to emphasize that the two methods of examination are not in competition with each other but are complementary to each other. Esophagoscopy has been found to be superior in the diagnosis of esophagitis, hemorrhagic erosions and gastritis within hernial pouches, telangiectasia, and in certain cases of esophageal varices and hiatus hernia. The x-ray examination, on the other hand, may be superior in the diagnosis of esophageal diverticula and in certain instances of esophageal varices and hiatus hernia. Also, it is important to bear in mind that both methods have their limitations, and the correct diagnosis may not be made until gastroscopy, surgical exploration, autopsy, or further observation. Obviously, the biggest advantage of esophagoscopy is the fact that the examination can be checked by biopsy, and in this regard it is important to emphasize that multiple biopsies and repeated examinations with biopsy may have to be done before a definite diagnosis is established.

Total	9	Total	9

We feel quite certain that such a study as this, with its attendant diagnostic benefit to our patients, would have been impossible without the introduction of this new safe optical instrument for the use of the gastroenterologic internist. We have encountered only one complication in this entire series of 197 examinations, and this was in a patient who developed minor bleeding from esophageal varices as a result of violent retching after the introduction of the instrument.

CONCLUSIONS

Whenever adequate roentgenographic examination fails to settle the diagnosis of esophageal and cardial disease, appropriate endoscopic procedures should be undertaken promptly. In this respect, a negative roentgenogram does not exclude esophageal or cardial disease with certainty. In special situations, gastroscopy is an important adjunctive procedure for the examination of the terminal esophagus and cardia, and, with the use of the newer and safer optical esophagoscopes, the usual delay and reluctance in accepting an important diagnostic procedure should be prevented.

CLINICAL NOTES

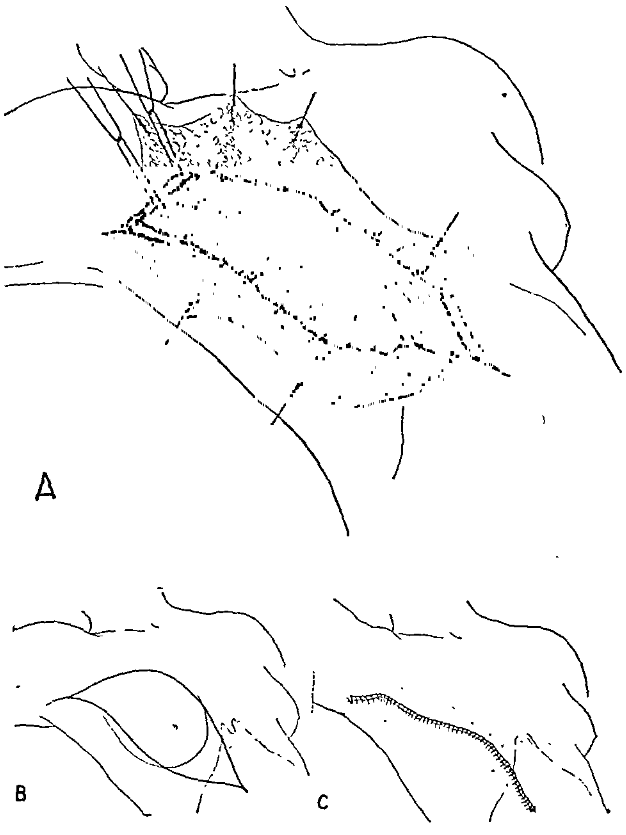
FIXATION OF SKIN FLAPS BY SUBCUTANEOUS SUTURES IN RADICAL MASTECTOMY

Bernard B. Larsen, M.D., Cleveland

Fixation of the skin to the chest wall and axillary fossa by means of subcutaneous sutures after radical amputation of the breast significantly decreases the morbidity of this operation. It has been long recognized by plastic surgeons that skin must be held securely in place if optimum healing is to be obtained. Following breast amputation, this has been a problem because of the almost constant motion of the chest wall and the depth and irregularity of the axillary fossa. Fixation of the skin to the chest wall and axilla by pressure alone has been only partially successful, although ingenious methods of applying external pressure have been employed.

Halsted,[1] in 1913, advocated fixation of the skin over the axillary vessels by suturing the skin edge to the deep structures. The covering flap was made short, so that the edge was sutured "to the fascia just below the first rib in such a way that the skin partly envelops the large vessels. The thoracic or inner wall of the apex of the axilla is always lined with skin grafts." More recently, Orr,[2] Leighton,[3] Keyes,[4] and others have recommended placing sutures through the skin into the deep structures to fasten the flaps in position. Raffl [5] has applied suction beneath the flaps to hold them more tightly in place. Fixation of the skin flaps by means of subcutaneous sutures has certain advantages over these methods.

Subcutaneous fixation sutures may be used following any type of radical breast amputation. I usually prefer an elliptical incision with the upper limit going obliquely across the axilla toward the posterior axillary fold. This affords a large upper skin flap to close over the axillary region. After the radical amputation is accomplished, the arm is placed in marked abduction and the skin flaps are then simply fixed to the chest wall and axilla by many subcutaneous fine cotton sutures to the deep muscles and fascia (see figure, *A*). From 35 to 50 such sutures are employed. Particular care is taken in covering the axillary vessels by suturing the upper flap first to the remaining clavicular portion of the pectoralis major muscle, then to the chest wall in the region of the first and second ribs, and then to the adjacent deep muscles. The flap is thus pulled high into the axillary fossa, obliterating all the major potential dead space. The arm held in marked abduction facilitates this part of the closure. The remaining flap areas are fixed to the chest wall by subcutaneous sutures placed approximately 5 cm. apart. When all subcutaneous sutures have been placed, the skin edges are close to approximation before the skin sutures are inserted. If the blood supply to the skin edges is excellent, a running lockstitch cotton suture is employed (see figure, *C*). If the blood supply is thought to be impaired somewhat, interrupted skin sutures are usually used. If the skin edges do not meet, split-thickness skin grafts are used to cover the defect. Drains are not inserted unless the chest wall is unusually wet or unless for some reason, a dead space persists. A large pressure dressing is applied, which is removed on the third postoperative day. At this time, the skin flaps are adherent, so a smaller, comfortable dressing is put in place, held by adhesive straps fitted with ties.



A, many subcutaneous sutures are placed into the muscles and fascia to fix the skin flaps in position and fill in dead spaces. *B*, area of incision. *C*, skin flaps are securely fixed in the axillary fossa and on the chest wall.

At this writing, this method of closure has been employed in 25 consecutive radical mastectomies with most gratifying results. Skin slough has been minimal. Pocketing of serum or blood has been unusual, even though drainage has not been employed except in the exceptional case. Extensive early movement of the shoulder has been more easily accomplished with less pain. Postoperative inflammation in the wound has been minimal, and it is reasonable to believe this will decrease the incidence of lymphedema of the upper extremity.

AURICULAR FIBRILLATION FOLLOWING PROLONGED USE OF THYROID EXTRACT

Emanuel Hellman, M.D., New York

Thyroid is administered in large quantities, in most instances unnecessarily, to patients all over the world. The extent to which the empirical use of such medication may be carried is shown in a recent article on the treatment of subdeltoid bursitis in which the author states, "The internist should review the patient generally and possibly prescribe thyroid or other hormones which in some instances appear to be effective."[1] In most cases no great harm results from such medication. Among the harmful effects that may result, particularly after prolonged administration of large doses, auricular fibrillation is most uncommon. The following case is therefore presented.

REPORT OF A CASE

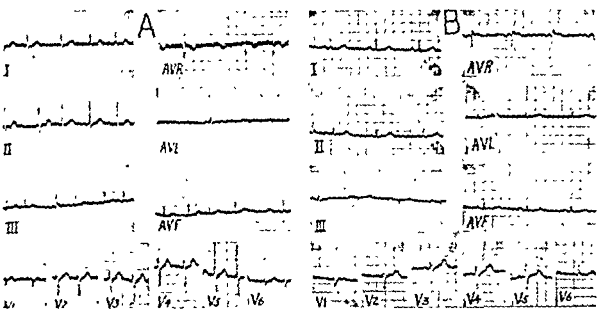
A 53-year-old female was referred for cardiac survey on Nov. 3, 1952. Her occupation required that she walk about most of the day. She stated that she had had intermittent, mild swelling of the ankles toward the end of the day for the past 20 years. About four weeks previously this swelling began to involve the legs as well as the ankles. There were no other cardiac symptoms. During this four week period she had received two injections of a mercurial, with considerable lessening of edema and weight loss each time. In 1946 she had sought treatment for mild obesity. Her basal metabolic rate at that time was reported as -10%. Therapy with 3 grains (0.2 gm.) of thyroid daily was started, and she had continued to take thyroid without interruption for six years prior to the date of examination. History was otherwise irrelevant.

Physical examination revealed a white female weighing 110 lb. (49.9 kg.) who did not appear acutely or chronically ill. Color was good and skin clear, not dyspneic or cyanosed. The throat was normal, and no adenopathy was revealed. The thyroid gland was not enlarged, and there was no exophthalmus. No neck vein distention was observed, and the eyegrounds were normal. There was a very fine tremor of the hands. The heart was not clinically enlarged. Blood pressure was 140/80 mm. Hg, and there was a grade 2 systolic murmur at the apex, not transmitted or influenced by change of position or exercise. The cardiac rhythm was grossly irregular, with a rate of approximately 100 beats per minute. The lungs were clear, the abdomen was normal, and there were no neurological findings. There was a 1 to 2+ pitting edema of both legs. Fluoroscopy revealed clear lung fields and normal cardiac contours. The urine showed a specific gravity of 1.022 and was negative for sugar and albumin. The red blood cell count was 4,600,000 per cubic millimeter and the white blood cell count 6,500 per cubic millimeter. The dimensions of the heart shadow as measured on a 6 ft. teleroentgenogram were within normal limits. A right oblique film taken after barium swallow revealed a normal left auricle. An electrocardiogram (see figure, *A*) revealed auricular fibrillation. There were no abnormalities of the ventricular groups diagnostic of myocardial disease.

The patient was placed on a low-salt diet and therapy with ¼ grain (15 mg.) of phenobarbital three times a day. Use of thyroid was stopped. The edema diminished progressively and completely disappeared within two weeks. On Dec. 12, 1952, the patient stated that she felt well, and it was noted that her cardiac rhythm was regular. The systolic murmur noted at the first examination had completely disappeared. An electrocardiogram (see figure, *B*) showed normal sinus rhythm, with no evidence of myocardial damage. The basal metabolic rate was -13% and blood cholesterol 250 mg. per 100 cc. On March 4, 1953, observation showed basal metabolic rate +1% and blood cholesterol 280 mg. per 100 cc. The patient remained clinically well, and there was no return of the auricular fibrillation.

COMMENT

The myxedematous patient responds to small doses of thyroid with a prompt rise in the basal metabolic rate and the serum protein-bound iodine, and these remain elevated as long as use of the drug is continued. Euthyroid subjects, however, show great individual variation in tolerance and response to prolonged administration of increasing amounts of the drug. In most euthyroid subjects, studies of basal metabolic rate, serum protein-bound iodine, and radioactive iodine uptake indicate that the activity of the thyroid gland is reduced under prolonged administration of thyroid.[2] In one patient with factitious thyrotoxicosis who was operated upon for toxic diffuse goiter (Graves' disease), the thyroid gland was found to be small, and biopsy was reported as showing "involution."[3] These observations are in keeping with experimental data that show suppression of thyroid activity and shrinkage of the gland after feeding of thyroid. It is thought that these effects are brought about by decreased secretion of thyrotropic hormone. In this connection it has been emphasized that endocrine glands in general may be set at rest and even caused to undergo atrophy by administration of large amounts of their specific hormones.



Electrocardiographic recordings of patient who developed auricular fibrillation following prolonged use of thyroid. *A*, auricular fibrillation with normal ventricular complexes (Nov. 3, 1952). *B*, regular sinus rhythm with normal ventricular complexes (Dec. 12, 1952).

The remarkable ability of the average euthyroid subject to develop tolerance to large doses of thyroid fortunately greatly reduces the incidence of hypermetabolism that might otherwise result from the prevalent indiscriminate use of thyroid preparations. On the other hand, the development of hypermetabolism simulating precisely the picture of full-blown thyrotoxicosis has also been reported in patients receiving large amounts of thyroid. Most instances of endogenous hyperthyroidism that are masked as heart disease are associated with auricular fibrillation. In general, auricular fibrillation occurs in 6 to 34% of hyperthyroid patients.[4] A search of the literature, however, yields only three previously reported cases of auricular fibrillation[5] and one case of auricular flutter[6] arising after thyroid administration to the euthyroid subject. In each case reversion to regular sinus rhythm followed cessation of use of the drug. In this connection it is interesting to note that studies of the effect of feeding large doses of thyroid to dogs, all of which develop signs of severe hyperthyroidism, showed that, while tachycardia occurred regularly, it was accompanied by actual disappearance of the normal respiratory arrhythmia that is characteristic of this animal.[7]

MECHANICAL DRAINAGE OF MASSIVE EDEMA

John B. Wild, M.D., Iowa City

Despite modern therapy edema sometimes proves to be a formidable problem, and recourse has to be made to mechanical means for removing excess fluid. The conditions in which intractable edema most commonly occur are congestive heart failure and nephrosis associated with low serum albumin, with or without a complicating hypertension. No claim is made that the method described is original, and no extensive search of the literature has been carried out. A large number of current and old textbooks have been consulted, and none of them mentions this particular technique. A number of them do not mention the mechanical drainage of edema fluid at all.

Two methods are commonly used for the mechanical removal of dependent subcutaneous fluid. The first is by the introduction of Southey's tubes into the subcutaneous tissue.[1] Long rubber tubes can then be attached to these and led into a basin at the patient's feet. The second method is by making multiple punctures through the skin into the subcutaneous tissue, allowing the fluid to drain from the skin. The use of Southey's tubes appeals because, in theory at least, the fluid can be led tidily away, and it is unlikely that organisms will gain access to the subcutaneous tissue up the long tubes down which the edema fluid is flowing. In practice, however, the tubes are likely to block and as much drainage takes place around them as through their lumens.

The principal objections to the use of multiple punctures through the skin are that they may be extremely painful and that there is a danger of sepsis. This danger is probably overemphasized, because mechanical drainage is not employed unless there is a great deal of edema fluid present; when punctures are made, the flow of fluid is considerable and tends to wash organisms away. When the flow is reduced the legs can be sponged three or four times a day with an antiseptic topically and a wide-spectrum antibiotic can be given parenterally. Pain may be reduced to a minimum by the use of the technique described below.

The apparatus used for making the multiple punctures consists of a piece of cork about 5 by 2.5 by 0.7 in. (12.5 by 6.2 by 1.8 cm.) through which four rows of three 20-gauge needles are thrust so that the points project by at least half an inch (see figure). The whole apparatus is autoclaved. The sites selected for puncture are the most dependent parts of the body where the edema is massive. These usually will be the dorsum of the feet and the medial and lateral aspects of the dorsum of the legs. The skin is scrupulously cleaned and sprayed with ethyl chloride until it is chilled. The operator then holds the battery of needles firmly in the palm of his hand and stabs the sites chosen; the points should penetrate about a quarter of an inch below the skin. If the operator's movements are swift, it should be possible to make 36 punctures in less than two seconds. The needles are not left in the skin but are removed as rapidly as they are inserted. It will be found that the patient feels as if he is being stuck with one needle each time the battery of punctures is made, provided the needles are used rapidly and forcibly.

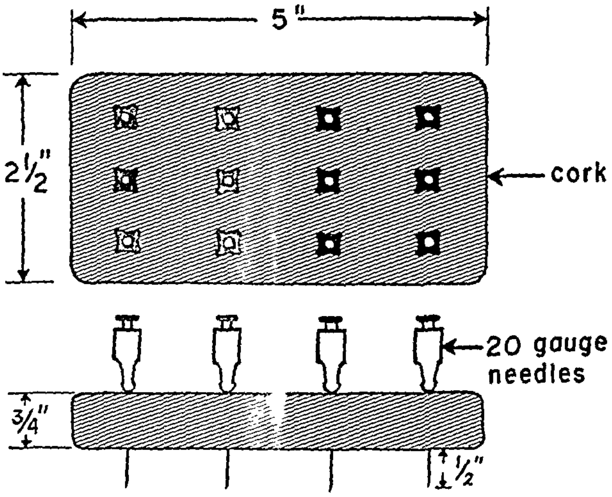

Diagram of apparatus for mechanical drainage of massive edema. Above, surface view. Below, side view.

The patient is then made to sit in an easy chair or cardiac bed with the legs dependent. If the edema fluid drained is to be measured, a rubber sheet is arranged behind the legs to channel the fluid into basins. Care should be taken not to allow the patient's feet to rest on the bottom of the basins because they will soon be soaking in edema fluid and will become cold and the skin will become macerated. The feet can conveniently be supported on a small stool. A broad-spectrum antibiotic is given for at least 24 hours longer than the legs drain, and the puncture sites are bathed with a mild antiseptic four times a day. Whether or not these precautions are necessary is not known, but one is loath to omit them. In the cases described below in which this technique was used, and in several others, no single case of sepsis that could conceivably be traced to the skin punctures was seen.

REPORT OF CASES

CASE 1.—An obese, dyspneic, orthopneic 51-year-old white woman suffering from nephrosis had massive edema of the legs, anterior abdominal wall, and sacrum. Widespread rales were heard in the chest except where there was a right hydrothorax. The heart was enlarged. The blood pressure was 170/100 mm. Hg. On admission the output of urine was scanty and contained 4+ protein. No erythrocytes or hemoglobin could be found in a centrifuged urine. The hemoglobin level was 13 gm. per 100 ml., and the white blood cell count was normal. The serum protein level was 5.1 gm. per 100 ml., the albumin level 2.95 gm., and the globulin 2.15 gm. per 100 ml. The blood urea nitrogen level was 99 mg. and creatinine level 6.7 mg. per 100 ml.

Mercurial diuretics were given intramuscularly on the first and second hospital days. The diuresis was satisfactory but made little impression on the edema, and it was obvious that this form of therapy would be extremely slow in removing the excess fluid. On the second hospital day 600 cc. of fluid was removed from the right pleural cavity. On the third hospital day multiple punctures were made in her feet and legs, and the fluid was collected in basins. In six days 13,250 cc. of fluid drained from the feet and legs. Her weight fell from 265.5 lb. to 232 lb. During this time she was eating a diet containing 150 gm. of protein. There was no sodium restriction and no diuretics were administered while the legs were draining. The urine output was satisfactory throughout, and the blood urea nitrogen fell to 70 mg. per 100 ml. and the creatinine level to 2.6 mg. per 100 ml.

The patient was discharged on March 12, 1954, weighing 240 lb. She continued with her high-protein diet for only three weeks and then could no longer tolerate it. Injections of mercurial diuretics three times a week produced good diuretic responses, but she started to gain weight and was readmitted on June 16, 1954. Her edema was once more considerable and the other findings were similar, except the blood urea nitrogen and creatinine, which were 19 mg. and 1.6 mg. per 100 ml. respectively. June 17 the legs and feet were again punctured, and a total of 6,050 cc. was collected in the next six days. Her weight fell from 257 to 229 lb. During this period she received mercurial diuretics with excellent response. She was discharged on June 30, weighing 221 lb. and feeling quite comfortable.

CASE 2.—A 50-year-old white woman suffering from severe, prolonged hypertension complicated by congestive failure had intractable edema that failed to respond to a low sodium diet and mercurial diuretics. For 17 days her weight varied between 167 and 151 lb. After her legs and feet were punctured, her weight fell from 151 to 110 lb. in four days. Her general condition very greatly improved, and she could walk about once more.

CASE 3.—A 46-year-old white woman with severe congestive failure complicating hypertension did not respond to a low-sodium diet and mercurial diuretics. For six days prior to the puncture of her feet and legs, her weight varied between 123 and 127 lb. Following puncture of the lower limbs, her weight fell to 113 lb. Thereafter she responded well to diuretics. She was discharged in 25 days weighing 109½ lb. and three months later during a routine check was found to weigh exactly the same.

CASE 4.—A 32-year-old white woman had severe congestive failure and edema complicating hypertension, diabetes, and albuminuria. Only the feet were punctured because of sepsis on the legs. In three days 3,275 cc. of fluid was collected. She died suddenly and unexpectedly on the fourth day after her feet were punctured. Permission for autopsy was refused.

CASE 5.—A 50-year-old Negro with hypertension and congestive failure showed no response to treatment with diuretics and sodium restriction. Three liters of fluid was collected in two days after puncturing the feet and legs. Thereafter there was a good response to the repeated use of mercurial diuretics.

COMMENT

I consider that the method I have described is the method of choice for the mechanical relief of edema fluid. I use it in the following circumstances: (1) when edema causes tension of the skin that is not rapidly relieved by more conservative therapy, (2) when there is no diuresis following the use of mercurial diuretics, (3) when mercurial diuretics are contraindicated, and (4) in order to shorten a patient's stay in hospital. The advantages of the method described are that the apparatus is simple, the time taken is minimal, and it can easily be employed in the patient's home when this is necessary.

SIMPLE PALPATION TO DETECT VALVULAR INCOMPETENCE IN PATIENTS WITH VARICOSE VEINS

Robert A. Nabatoff, M.D., New York

During recent years, practically every report concerning the treatment of varicose veins has emphasized the importance of a proper high ligation of the long saphenous vein. This implies that the long saphenous vein is ligated flush with the femoral vein after all of its adjacent branches are ligated and divided. Unfortunately, in a significant number of cases, the dissection is not carried high enough. Unless the femoral vein is visualized, branches of the saphenous vein near the saphenofemoral junction may be overlooked, and it is these vessels that usually cause recurrent varicosities. The predominant venous insufficiency is usually at the saphenofemoral junction, but there may be incompetent valves in other communicating vessels of the thigh or leg or at the short saphenous vein–popliteal vein junction. The success of operation depends upon the ability of the surgeon to detect and eliminate all sites of valvular incompetence.

Many diagnostic tests have been devised to aid the physician in the detection and localization of "blowouts." The tests most commonly used are: (1) Brodie-Trendelenburg, (2) comparative tourniquet (Ochsner-Mahorner), (3) Perthes', (4) compression, and (5) Schwartz (percussion) test. Performing and interpreting these tests is a rather formidable and time-consuming job for the average student or practitioner. According to Steiner and Palmer's findings,[1] the Perthes', compression, and Schwartz tests have little to offer, are unreliable, and reveal no information that cannot be obtained by more accurate methods. "It would seem that the Brodie-Trendelenburg test, with the additional feature of the tourniquet placed just above the level of the knee . . . will actually afford all of the information required for one to treat any uncomplicated case of varicose veins." Luke [2] also believes that valvular incompetence can be determined by the Brodie-Trendelenburg test and that the other modifications of this test are unnecessary in the evaluation of any case of primary varicose veins. He states: "The modifications of the Trendelenburg test were designed to indicate the competence of communicating veins. In theory this would appear to be quite worthwhile; however, in practice, one cannot rely on such findings. In addition, when the operation of stripping of the great and small saphenous veins is carried out, most incompetent communicating veins are automatically interrupted. Thus, the modifications of the Trendelenburg test, such as the comparative tourniquet or multiple tourniquet tests, become unnecessary."

---

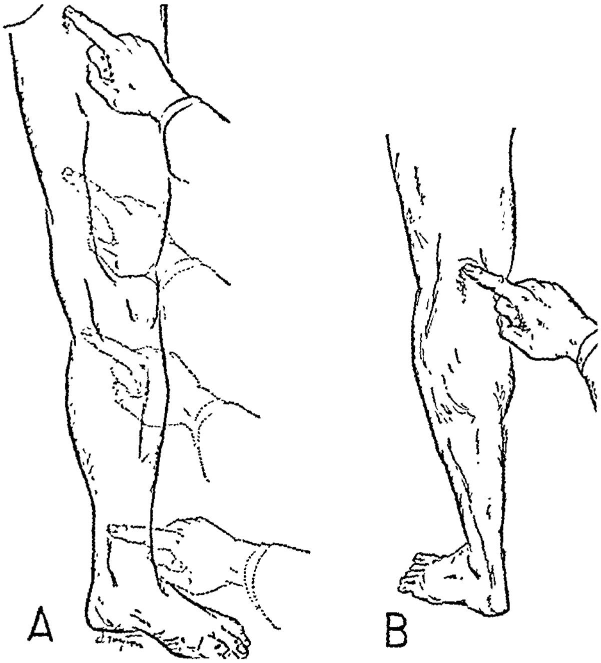
[2] Luke, J. C.: Venous Disorders of the Lower Extremity, Ciba Clin. Symposia **5**: 100-124, 1953.

As the result of examining many patients with varicose veins, it has become apparent that in practically all cases of saphenofemoral insufficiency, a definite "bulge" can be palpated in the region of the fossa ovalis (see figure, *A*). This has even been true in obese patients. If the tip of the index finger is placed just below the inguinal ligament, just mesial to the femoral artery, the "bulge" is easily palpated. In order to detect any valvular incompetence below this level, the tip of the index finger is run slowly down the thigh and leg along the course of the saphenous vein. If other "blow-outs" exist, a sudden increase of the pressure within the saphenous vein will occur immediately below the site of each incompetent valve. It has been my experience that the vast majority of patients with varicose veins have their predominant insufficiency at the saphenofemoral junction.



The use of simple palpation to localize sites of valvular incompetence in patients with varicose veins. *A*, the tip of the index finger palpates the area just below the inguinal ligament, just mesial to the femoral artery. In patients with saphenofemoral insufficiency, a definite venous "bulge" is invariably palpable. The finger is then run slowly downward along the course of the long saphenous vein. Any abrupt increase of the pressure within the vein usually indicates an incompetent valve immediately above this level. *B*, a similar test used to detect incompetence at the short saphenous-popliteal vein junction. If significant venous insufficiency is present, a definite "bulge" can be palpated in the center of the popliteal space. The finger is then run downward along the course of the short saphenous vein to detect any other "blow-outs."

In order to detect valvular incompetence along the short saphenous system, the popliteal space is palpated. If short saphenous-popliteal vein insufficiency exists, a "bulge" can usually be palpated in the center of this space (see figure, *B*). The finger is then run downward along the course of the short saphenous vein in order to detect any further "blow-outs." As a rule, the incompetence in the short saphenous system has its origin at the saphenopopliteal vein junction. Therefore, at the time of surgery, it is important to ligate the short saphenous vein flush with the popliteal, after all adjacent branches have been divided.

In the vast majority of patients with varicose veins, all venous incompetence originates along the long or short saphenous vein. Occasionally there will be an atypical "blow-out." This can be easily detected by simple inspection and palpation of the thigh and leg. It has been our practice to have the patient stand for several minutes so that the veins may assume their greatest prominence. The tip of the index finger is then run along the course of the long and short saphenous veins. Each site of valvular insufficiency is localized and accurately mapped out.[3] It has been my experience that accurate localization of all perforators can be carried out without the addition of any further diagnostic tests.

CONCLUSIONS

The use of simple palpation has been found to be accurate in the detection of sites of valvular incompetence. It has not been necessary to use tourniquet tests or other complicated maneuvers. The palpation technique is simple to master and takes only a few minutes to carry out. It greatly facilitates diagnostic study in patients with varicose veins.

1150 Park Ave. (28).

Estrogen Therapy.—The objective of estrogen therapy is to reduce the intensity of distressing symptoms, as well as to tide the patient over a period of physiologic adjustment. Orally taken estrogen is particularly suited to menopausal therapy, and there is no need for its parenteral administration. A positive advantage of oral therapy is the fact that a distinctly smoother control of symptoms may be obtained with any of the estrogens by the taking of one or more doses daily than by any of the ordinary injection procedures at intervals of a week or more. The smallest oral dose required to assuage vasomotor symptoms should be prescribed according to definite rules. Whether one employs a daily dose of 0.625 mg. of estrone sulfate, 0.2 mg. of dienestrol, 0.5 mg. of stilbestrol, or 0.02 mg. of ethinyl estradiol is immaterial. The important precepts are to prescribe the estrogen for a limited period and to withdraw it in gradual manner. The most prevalent abuse in the usage of estrogen, aside from needless employment of estrogenic injections, is the prescription of a routine dose to be taken daily more or less indefinitely. It must be re-emphasized that the objective of estrogen therapy of the menopausal syndrome is to aid the patient's adjustment to the diminution and eventual cessation of ovarian function. This logical aim is lost if the estrogen is not prescribed for measured periods, with repeated attempts to withdraw the hormone entirely. It's about time that we spend more time mitigating menopausal anxiety and less time prescribing estrogen as an "all-purpose female tonic."—S. Leon Israel, M.D., *Journal of the Albert Einstein Medical Center,* November, 1954.

FAMILIAL HEREDITARY PURPURA SIMPLEX WITH SCHÖNLEIN-HENOCH SYNDROME

RESPONSE TO CORTICOTROPIN (ACTH), CORTISONE, AND ANTIHISTAMINICS

Niel Wald, M.D.
and
Milton Kissin, M.D., New York

Purpura simplex is a term applied to mild spontaneous purpuric skin manifestations with no hematological abnormality and with the Rumpel-Leede phenomenon frequently present. The condition occurs almost only in women, rarely in children, and is often familial. It has been well recognized since the descriptions by Willan and Bateman early in the 19th century. The hereditary feature was first noted by Bauer in 1868. Davis[1] gave the name *hereditary familial purpura simplex* to this syndrome, which occurred in 88 members of 27 families studied in London. Soulier[2] in France confirmed Davis' findings and noted bleeding in mucous membranes as well as in the skin. In five of Davis' families[1c] a case of Schönlein-Henoch purpura was noted. In Bauer's family study, reported in 1868, one of three sisters having purpura simplex developed severe visceral hemorrhages and died at 22 years of age (perhaps of Henoch's purpura).

Schönlein-Henoch syndrome is the term applied to a condition in which nontraumatic bleeding with or without edema occurs in the absence of hematological abnormality in one or more of the following areas: skin, subcutaneous tissue, mucous membranes, joints, and viscera. First described by Willan in 1808, its skin and joint manifestations were recorded in 1837 by Schönlein, its gastrointestinal disturbances pointed out by Henoch in 1874, and its multiplicity of symptoms and etiologies clarified by Osler. It is currently regarded as an allergic phenomenon, characterized pathologically by increased capillary permeability and produced by sensitivity to bacteria, foods, drugs, or unknown factors. It usually occurs in children and young adults of both sexes and is not ordinarily considered familial, although a syndrome with its characteristics has been described in five generations of a family.[3] The following case is presented to call attention to the possible coexistence of the two syndromes since hereditary familial purpura simplex with Schönlein-Henoch syndrome has not been described in the United States. In addition, the efficacy of corticotropin (ACTH), cortisone, and chlorpheniramine (Chlor-Trimeton) maleate, with relapse following withdrawal of each, seems worthy of note.

REPORT OF A CASE

A 24-year-old white woman was first hospitalized at Beth Israel Hospital on Jan. 8, 1952, with a nine day history of a rash, consisting of small red spots over the legs and with some itching. The rash extended to the buttocks, back of neck, and face, with intermittent progression and recession. At the same time, pain and decreased mobility of fingers, ankles, knees, and shoulders developed, with some ankle swelling. The temperature ranged from 100 to 101 F evenings. Chloramphenicol (Chloromycetin), 250 mg. every six hours for 10 doses, did not alter symptoms.

Except for an annual "summer cold," the patient had been well until 1947, when at irregular intervals of three to six months she developed episodes of petechiae on the arms, pain in the knees and back of legs, low-grade fever, and leukocytosis with a normal erythrocyte sedimentation rate. These attacks generally lasted several days. Sharp abdominal pain was noted during some of these episodes and sometimes independently. Persistent coldness and hyperhidrosis of extremities were also noted. In March, 1948, the patient underwent appendectomy because of right lower abdominal pain, fever, and a leukocyte count of 18,500 per cubic millimeter. The pathologist reported a "grossly normal appendix with an intact mucosa." Some blood was found in the lumen and there were subserosal congested vessels with "no associated inflammatory reaction." In June, 1948, the patient was given a sulfonamide for an upper respiratory infection. She developed severe cough, slight hemoptysis, purpura, and fever. A month of tuberculosis rest therapy followed despite negative tests for tuberculosis. The same episodes persisted. Brucellosis was considered, and the patient finally was referred for psychiatric therapy. Although some benefit was obtained, the above-described picture was not altered. Several months later, the heterophil titer for suspected infectious mononucleosis was negative. The family history revealed the presence of one or more of the following symptoms in many of the female adults over three generations: profuse bleeding due to trauma, epistaxis, urticaria, joint pain and swelling, abdominal pain, heart murmur, and spontaneous ecchymoses. (See figure and table. Persons designated as B, C, L, and M were examined by one of us [N. W.].) None of these symptoms and signs were present in the history of any of the males.

Geneological presentation of pertinent symptoms in family of patient studied.

Physical examination revealed the following positive findings: temperature 100.4 F, pulse rate 112 beats per minute. There was a petechial morbilliform rash over the lower part of both legs and to a lesser degree on the face and back. The heart rhythm was regular, with a rate of 112. A faint blowing systolic murmur was heard at the cardiac apex. The liver edge was palpable 1 cm. below the costal margin. Minimal swelling of the third and fourth phalanges bilaterally was noted.

Laboratory Data.—Urinalysis was negative. The hemoglobin level was 13 gm. per 100 cc. (84%), leukocytes 15,000 per cubic millimeter, polymorphonuclear cells 77%, stab forms 2%, lymphocytes 11%, eosinophils 4%, monocytes 6%; platelets 169,000, and erythrocyte sedimentation rate 5 mm. in one hour. The blood glucose level was 99 mg. per 100 cc., blood nonprotein nitrogen 27 mg. per 100 cc., and serum protein 6.79 mg. per 100 cc., with albumin 4.9, globulin 1.8, and the albumin-globulin ratio 2.7. The thymol turbidity was 3.7 units and cephalin flocculation 2+ in 48 hours. The plasma ascorbic acid level was 2.16 mg. per 100 cc.; prothrombin time, modified

prothrombin consumption time,[4] bleeding time, Lee-White clotting time, and clot retraction were all normal. Kahn and Wassermann serologic tests were negative. The electrocardiogram and chest x-ray were normal. The Rumpel-Leede phenomenon was markedly present.

Clinical Course.—The clinical diagnosis of Schönlein-Henoch purpura in a patient with familial hereditary purpura simplex was made. The patient was given corticotropin intravenously in 1,000 cc. of 5% glucose solution over a period of 10 hours on Jan. 13, 1952. There was marked improvement after the first dose. The following day, the same treatment was given, with complete disappearance of all signs and symptoms. Dosage of corticotropin was tapered off in 5 mg. decrements. The Rumpel-Leede phenomenon became absent. After a final dose of 2.5 mg., the patient was discharged on Jan. 17, 1952.

Second Admission.—The patient was well for two days; then recurrent arm and shoulder pain and stiffness as well as swelling of fingers developed, and spontaneous ecchymoses of thighs were noted. Acetylsalicylic acid was administered without any effect on symptoms, until tinnitus and vomiting supervened, and the patient was readmitted on Jan. 23, 1952. Physical examination revealed a temperature of 99.6 F; tenderness and pain of neck, shoulders, elbows, wrists, and fingers, and mild interphalangeal joint swelling with limitation of motion.

The Rumpel-Leede phenomenon was again present. Twenty milligrams of corticotropin intravenously gave complete remission. The dosage was tapered rapidly, therapy changed to cortisone, and the patient was discharged on Jan. 28, 1952, on a regimen of 25 mg. cortisone four times daily. This was reduced gradually to 12.5 mg. daily, and in two weeks therapy was stopped. The Rumpel-Leede phenomenon became absent. The patient remained symptom-free until about a week later, when mild ankle and knee pain recurred as well as interphalangeal stiffness and swelling. Tripelennamine (Pyribenzamine), 50 mg. every four hours, controlled these symptoms in one day but evoked unpleasant side-effects of nausea and somnolence. Therapy with chlorpheniramine, 4 mg. given four times daily, was instituted, with complete clinical relief of symptoms and absence of the Rumpel-Leede phenomenon. After several weeks, this therapy was discontinued, and the patient was asymptomatic for the three months that she was followed without therapy; however, the Rumpel-Leede phenomenon again was mildly present.

COMMENT

Both the Schönlein-Henoch syndrome and familial hereditary purpura simplex are relatively benign conditions, the latter even more than the former, in which the establishment of the diagnosis is of greatest importance because of the resultant prevention of unnecessary or erroneous treatment. In this case, diagnoses entertained prior to hospitalization included pulmonary tuberculosis, acute appendicitis, infectious mononucleosis, brucellosis, psychoneurosis, secondary syphilis, and rheumatic fever.

The coexistence of these two syndromes as noted by Davis,[1] and in our case, suggests some common etiological relationship. Another point in favor of some common denominator is revealed by a review of the diseases that have been found related to each of these two entities. Davis points out, in the literature and in his own series,[1] a significant association between familial hereditary purpura simplex and both rheumatic fever and rheumatoid arthritis. In our family study, there are three persons with known heart murmurs, five persons with transient joint pains and swelling, and one with definite joint deformities. Schönlein noted a high incidence of rheumatic sufferers among patients having the syndrome that bears his name. Since then, Osler and many others [5] have suggested a linkage with anaphylactic states, acute nephritis, rheumatic fever, and polyarteritis nodosa. Quick [6] suspected a close relation with thrombocytopenic purpura.

A common pathogenic factor noted in all these diseases is alteration of capillary endothelium with resultant increased permeability, perhaps with a hypersensitive state. Since adrenal cortical stimulation with corticotropin, and cortisone have been shown to increase capillary resistance by Robson and Duthie [7] and others,[8] corticotropin was used therapeutically with excellent rapid response followed by prompt relapse on subsequent cessation of therapy. This same sequence was repeated once again with corticotropin and then with cortisone. The same beneficial effect was noted by Stefanini and others [9]

and Kugelmass [10] in Schönlein-Henoch syndrome and by Hewlett and Scott [11] in 12 patients with assorted thrombocytopenic states. In view of the often suggested possibility of an allergic basis for this syndrome, antihistaminics were tried. Tripelennamine and chlorpheniramine therapy was used, with good response. A similarly good result has been reported by Keenan.[12] The lack of a clinical relapse on cessation on antihistamine therapy suggests that the present episode may have run its course; however, the rapid onset of effect and the post-therapy return of the positive Rumpel-Leede phenomenon in our case, as well as the good response of Keenan's patient to tripelennamine would seem to indicate that these medicaments, too, are sometimes effective in temporarily restoring normal capillary endothelial integrity.

SUMMARY

Schönlein-Henoch syndrome was found to coexist in an individual with familial hereditary purpura simplex. Altered capillary endothelium is a common pathogenic factor in these syndromes. Therapy with corticotropin (ACTH), cortisone, and antihistamines is beneficial.

NEW REGIONAL ANESTHETIC TECHNIQUE FOR ADULT CIRCUMCISION

Stuart Light, M.D., Chicago
Glenn R. Weygandt, M.D., Peoria, Ill.
and
Lieut. Bernard V. Wetchler (MC), U. S. Army

Adult circumcision is a minor procedure for which a safe, simple, and satisfactory local anesthetic technique is difficult to come upon. Although many different regional methods have been described,[1] they do not always result in a pain-free procedure, and frequently more agent than is necessary has to be used. Labat [1a] and Tuohy [1b] attribute tissue slough to local infiltration (particularly around the prepuce); whereas Fruin and McLaughlin [2] feel it is the cause of excessive postoperative edema and tardy healing. As a result of this, many clinics have had to resort to either spinal or general anesthesia, thereby greatly increasing operative and postoperative morbidity. For this procedure (which so often is done at the office), we feel that only a local anesthesia should be used. A regional method will be presented, which we believe fulfills all of the requirements for the ideal circumcision anesthetic.

INNERVATION

Many men are of the opinion that the dorsal nerves alone are responsible for the cutaneous innervation of the penis. This is not so. The nerve supply of the penis is derived from the pudendal nerve. It divides into two main branches, the dorsal and perineal nerves. The dorsal nerves supply the skin of the dorsolateral aspects of the penis and send terminal filaments to the glans. The perineal nerve subdivides into posterior scrotal and muscular branches.[3] We believe these posterior scrotal branches send out fibers that run paraurethrally, supplying sensation to the ventral portion of the penis and the mucous membrane of the urethra. We have attempted by selective nerve blocks to show this dual nerve supply to be present. By injecting the dorsal nerves with procaine hydrochloride, sensory anesthesia of the dorsal and lateral aspects of the penis and the entire glans with the exception of the prenulum was obtained. Paraurethral injections blocked sensation to the ventral penile surface and also rendered the frenular area and the urethral mucosa insensitive to stimuli. These four nerves, two dorsal and two paraurethral, are injected in our procedure.

CONSIDERATIONS OF THE PROCEDURE

Premedication.—The use of adequate sedative and hypnotic drugs preoperatively cannot be overly stressed in adding to the success of any regional procedure. Proper timing is of particular importance. Our patients were all given 100 mg. of secobarbital (Seconal) the night preceding surgery. On the operative day, 60 to 90 minutes prior to surgery, the patient received: secobarbital, 100 mg.; meperidine (Demerol) hydrochloride, 100 mg.; and scopolamine hydrobromide, 0.4 mg.

Solutions Used.—Procaine hydrochloride 1% was used in all cases. Sufficient epinephrine (Adrenalin) was added (5 drops of 1:1,000 epinephrine, delivered through a 22 gauge needle, to 20 cc. of 1% procaine hydrochloride) to produce a 1:200,000 concentration. This syringe should not be used for the block. A greater concentration of epinephrine may result in an almost bloodless operation, thereby increasing the possibilities of postoperative bleeding once the vasoconstriction has subsided. Epinephrine, 1:200,000, yields an optimum effect, should cause no untoward reactions, and is essential to the success of the procedure.

Method.—The operative area is cleansed. The dorsal nerves are blocked at the base of the penis. A 23 gauge

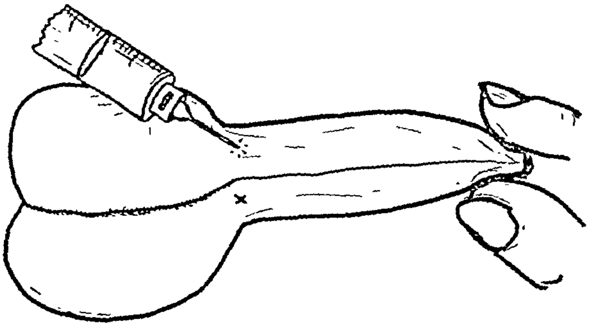
[3] Morris, H.: Human Anatomy: A Complete Systematic Treatise, edited by C. M. Jackson, ed. 9, Philadelphia, P. Blakiston's Son & Company, Inc., 1933, p. 1097. Gray, H.: Anatomy of the Human Body, edited by W. H. Lewis, ed. 24, Philadelphia, Lea & Febiger, 1942, p. 985. Sobotta, J.: Atlas of Human Anatomy, English ed. 2, from German ed. 6, edited by J. P. McMurrich, New York, G. E. Stechert & Company, 1928.

needle is inserted perpendicularly through the skin on either side of the midline until a definite sense of resistence is experienced. For each side 3 cc. of 1% procaine hydrochloride is injected. If the needle pierces the corpus, pain will result. The penis is then pointed cephalad, so that its ventral surface is uppermost, and 2 cc. of 1% procaine is then injected bilaterally (at the base) into the grooves formed by the corpora cavernosa penis and the corpus spongiosum (see figure). These paraurethral injections are more easily accomplished by having the patient maintain gentle traction on the prepuce to keep the penile skin taut. A waiting period of up to 10 minutes is occassionally necessary before surgery can start. However, once the penis shows signs of sensory loss, the block will always be satisfactory. If the solutions are properly placed, analgesia is obtained almost immediately. Block of any of the four nerves may be repeated if necessary.

RESULTS

There have been no cases in which the anesthesia was unsatisfactory. This technique has been used in over 1,000 cases, including urethroplasties and procedures directly on the glans, without any operative or postoperative complications attributed to the anesthesia. No more than 10 cc, of 1% procaine hydrochloride should be used. We have been able to get excellent results using as little as 6 cc. of solution (2 cc. in each dorsal nerve and 1 cc. in each paraurethral space). We consider our method to be a perfectly safe anesthetic for office use.



Technique of block of paraurethral nerves.

SUMMARY AND CONCLUSIONS

Many of the local infiltration techniques used for adult circumcision do not yield a pain-free procedure, may use excessive local agent, and occassionally result in tissue slough and postoperative edema. A regional method combines ease of administration with uniformly excellent results, having been used in over 1,000 cases. It involves blockage of the dorsal and paraurethral nerve supply to the penis. The local drug in all cases was 1% procaine hydrochloride with epinephrine 1:200,000. The maximum amount of procaine hydrochloride necessary for any one patient should be 10 cc.; as little as 6 cc. has produced operative anesthesia. This technique has proved safe, simple, and satisfactory from both the anesthetic and urologic standpoints.

2718 Grand Blvd., Peoria, Ill. (Dr. Wetchler).

DIAGNOSTIC PROBLEMS

PRESENTATION OF CASE

John D. Thorpe, M.D., St. Louis

A 64-year-old widow entered Barnes Hospital, St. Louis, on Nov. 18, 1954, complaining of "bloating and belching" of about one month's duration. This was associated with intermittent pain in the left upper abdominal quadrant and anorexia. Later the pain radiated to her back. In the month preceding admission she had lost 10 lb. (4.5 kg.). Four days before she was admitted to the hospital her stools became gray and her skin became yellow.

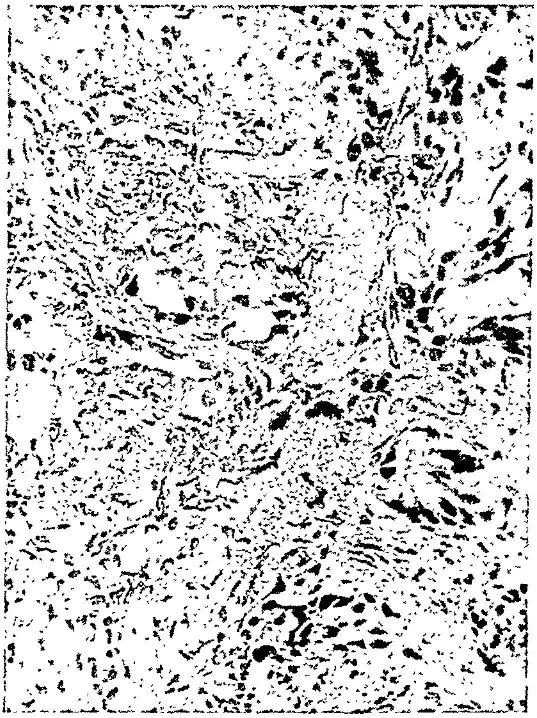


Fig. 1.—Photomicrograph of frozen section of needle biopsy specimen of pancreas, showing poorly differentiated adenocarcinoma growing in a background of fibrous tissue.

Physical Examination.—On admission her systolic blood pressure was slightly elevated; her skin and sclerae were icteric, and a loud grade 2 apical systolic murmur was heard. Her abdomen was not tender, but the liver edge was palpable 3 cm. below the right costal margin and was slightly tender. A tentative diagnosis of obstructive jaundice, with possible early carcinoma of the head of the pancreas, was made.

Laboratory Findings.—Blood cell counts revealed a mild anemia. The urinary bile pigments were increased. A stool was negative for occult blood and was grayish-white. Blood chemistry and liver function studies were

---

From the Department of Surgical Pathology, Washington University School of Medicine.

consistent with obstructive jaundice. Complete gastrointestinal roentgenographic studies including gallbladder showed nonvisualization of the gallbladder. Subsequently the jaundice deepened and glucose tolerance tests, starch tolerance tests, and blood sugar determination indicated a diffuse involvement of the pancreas, possibly with tumor.

Course.—The patient was transferred to the surgical service, and an exploratory laparotomy was performed on Nov. 29, 1954. A mass the size of a golf ball was palpable in the head of the pancreas; the remaining pancreas was found to be indurated. A single lymph node in the gastrohepatic ligament was excised. Frozen section of this node showed no evidence of tumor. Frozen section of a superficial incisional biopsy specimen of the pancreatic mass showed pancreatitis. The duodenum was opened at the suggestion of the pathologist, and the ampulla of Vater was found to be normal in gross appearance. A Vim-Silverman needle was introduced from the duodenum into the pancreas, and frozen section of this needle biopsy material revealed carcinoma. Subsequently paraffin sections of the incisional biopsy specimen of the pancreatic mass also revealed carcinoma. A modified Whipple procedure was then carried out with surgical excision of the head of the pancreas, gallbladder, and the second portion of the duodenum. An anastomosis of the remaining pancreatic duct, common bile duct, and the stomach with the jejunum was made. The surgical specimen revealed a poorly differentiated adenocarcinoma with nerve sheath invasion and invasion of the excised portion of the duodenum (see figure). In six regional lymph nodes there was no evidence of metastasis.

In the immediate postoperative period, the patient did well. Convalescence was uneventful, and she was discharged 16 days following operation. She continued to do well and slowly gained weight until Feb. 25, 1955, when she returned to the hospital complaining of chills and fever, which had followed an upper respiratory infection. Despite antibiotics, her fever persisted, and she was readmitted to the medical service. At this time she had an elevated leukocyte count and hepatic function tests were within normal limits. The medical staff believed the patient had an ascending cholangitis, secondary to her operation. Because her febrile course continued, with little response to intensive antibiotic therapy, an exploratory laparotomy was performed. At this second operation two large masses were found in the liver. There was no obstruction referable to the previous operation, although much scarring was present. A biopsy specimen of the tumor mass in the liver showed metastatic carcinoma from the pancreas. Postoperatively her wound healed well, and three weeks later super-voltage roentgenotherapy using the betatron was begun over the area of the liver metastases. A total of 3,600 r was given over a period of two weeks. There was little subjective side-effect of the irradiation, and the patient was discharged, to be followed in the clinics.

COMMENT

Robert Elman, M.D., St. Louis

This experience illustrates several of the problems in pancreatic cancer. Operations entailing pancreatoduodenectomy are still formidable; this is particularly true with regard to cancer of the head of the pancreas. The high postoperative mortality rate and the poor long-range prognosis make this undertaking one that must be carefully planned and executed by a skillful surgeon. The reported cases of five year survivals for cancer of the head of the pancreas can easily be counted on the fingers of one hand; the results for cancer of the ampulla of Vater are somewhat better. In the face of such adverse experiences, the surgeon should have at his command all of the diagnostic assistance possible prior to completing any radical procedure. Chronic pancreatitis and carcinoma of the pancreas may mimic one another both in clinical findings and in gross appearance at operation. Frozen section at this time is mandatory, and the extensive surgical procedures necessary in pancreatoduodenectomy should not be carried out until a positive diagnosis of cancer is obtained.

In the event of a negative biopsy of the pancreas, the duodenum should be opened and the ampullary region investigated, because the obstructive lesion may arise in this location. Frozen section of the pancreas can be misleading because a tumor is often deeply situated and surrounded by a dense zone of inflammatory reaction. Carlson [1] and Probstein [2] cite examples of a radical operation on patients with only presumptive evidence of malignancy, whose lesions later proved to be benign. The pathologist should also be aware of the errors inherent in frozen section diagnoses in this region. Since the consistency, gross appearance, and degree of fixation of the suspected lesion are of little help in differentiating between pancreatitis and tumor, the surgeon is faced with the choice of a shunting procedure to relieve symptoms or a more extensive and radical resection. This choice is both difficult and important, for, despite the sporadic reports of five year survivals, it is only the more radical procedure that will give the patient a chance of an arrest of his disease if it proves to be malignant. Although the diagnosis of cancer was clearly suspected at the bedside in the case presented, the paucity of more exact methods emphasizes the need for exploration in many patients with jaundice the cause of which is otherwise difficult or impossible to determine.

It is difficult or impossible to establish the nature of a palpable pancreatic tumor found at operation to be the cause of jaundice. In this particular case the rounded, circumscribed mass was to palpation so much more characteristic of a neoplasm than the more diffuse induration of chronic pancreatitis that resection was decided on despite the negative results of the frozen section obtained by biopsy through the anterior surface of the

mass. Such biopsies are not always helpful because they may be negative in the presence of a deeply lying tumor or negative in the frozen but positive in the paraffin section as in this case. The experience reported here is unusual. A positive diagnosis by frozen section was reported in 39 of the last 41 biopsy specimens removed at operation in patients subjected to pancreatoduodenectomy for pancreatic carcinoma.[3] The recommendation of the pathologist to open the duodenum was a good one and should be made more often. Duodenotomy is useful diagnostically when it reveals disease at the ampulla or ulceration of the duodenum and in this case it led to a positive diagnosis. It is not surprising that this kind of biopsy was more revealing since the center of the tumor at this site is more accessible, although the use of the long needle may have been just as important. It is also probable that far less danger attends biopsy performed from within the duodenum than that through the external surface of the pancreas. We have seen repeatedly that duodenotomy is a safe and often a rewarding maneuver during operation in selected patients with biliary tract and pancreatic disease.

The rapid downward course of this patient despite adequate excision is tragic evidence that even with early operation, a history of symptoms of short duration does not necessarily give promise of a good result but rather may mean a rapidly growing tumor and a poor prognosis. All biologists know that regardless of therapy prognosis depends largely on the variable rate of growth of cancer (or conversely the variable resistance of the patient). Thus the small localized tumor readily and widely removed early may already have metastasized, whereas the large tumor with involved but accessible regional lymph nodes may still offer a good prognosis after adequate excision. Whether undue manipulation or biopsy of the tumor in the present case accelerated the tendency toward the rapidly developing hepatic metastases cannot be proved, but it reminds us that any mechanical trauma to malignant tissue is fraught with the danger of promoting spread.

Anticoagulants.—The realization that the anticoagulant treatment of thromboembolic disorders is a controversial subject brings up the question for the general practitioner as to how to proceed with his treatment of acute thromboembolic accidents, especially acute coronary occlusion. . . . If he is not familiar with the action of these drugs or does not have the necessary laboratory facilities, he would be wise to abstain from their administration. If, on the other hand, he feels competent to apply such therapy he must use it discriminately, according to the condition of his patients. He may follow those authorities who have a more aggressive attitude, or others with a more conservative approach. Statements that the "omission of anticoagulants in a case of acute myocardial occlusion creates a medical liability" are just as unfortunate as remarks that "the sole reason for prophylactic use of anticoagulants is the fear of litigations." Such opinions will create confusion among the medical profession. Let us all realize that the available anticoagulants may have faults and shortcomings, but represent at this time the best approach to the treatment of thromboembolic disorders.—H. B. Eisenstadt, M.D., and B. B. Elster, M.D., Are Anticoagulants Too Dangerous for General Use? *American Practitioner and Digest of Treatment,* July, 1955.

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

R. T. STORMONT, M.D., *Secretary.*

Lente Insulin.—"Lente insulin is a sterile suspension, in a buffered water medium, of insulin modified by the addition of zinc chloride. Of the insulin contained in the preparation not more than 1 U. S. P. Unit of insulin per milliliter is in solution, approximately 70 per cent is crystalline, and the remainder is amorphous. Zinc-insulin crystals are used in such quantity that each milliliter of the preparation, when the precipitate therein is brought into uniform suspension, contains either 40 or 80 U. S. P. Units of insulin. The preparation contains, for each 100 U. S. P. Units of insulin not less than 0.20 milligram and not more than 0.25 milligram zinc (of which not less than 40 per cent nor more than 65 per cent is in the supernanant liquid), and not more than 0.65 milligram nitrogen. The preparation also contains not less than 0.15 per cent and not more than 0.17 per cent (w/v) sodium acetate, not less than 0.65 per cent and not more than 0.75 per cent (w/v) sodium chloride, and not less than 0.09 per cent and not more than 0.11 per cent (w/v) methyl-*p*-hydroxybenzoate. The pH of the finished product is not less than 7.1 nor more than 7.5." Certification of Batches of Drugs Composed Wholly or Partly of Insulin (19 Fed. Reg. 4153 [July 8] 1954).

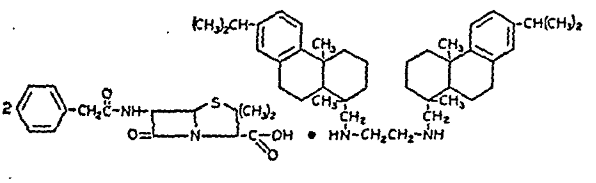
Actions and Uses.—Lente insulin is a mixture of minute particles consisting of approximately 70% crystalline zinc insulin and 30% amorphous zinc insulin, each component of which has a sufficiently high zinc content to make the mixture relatively insoluble at the pH of the blood. The proportion of the components provides an antidiabetic action that is intermediate in time between that of unmodified (regular) insulin and protamine zinc insulin. The time of action of lente insulin so closely approximates that of the modified protamine zinc insulin, isophane (NPH) insulin, that they can be used interchangeably. The onset of action of lente insulin is sufficiently prompt to control the after-breakfast rise in blood sugar, and its duration of activity is usually adequate to maintain blood sugar levels during fasting without the need for supplementary injections. Lente insulin, which contains no foreign modifying protein, is free from the possibility of producing local sensitivity reactions attributed to protamine or globin. Since lente insulin differs clinically from unmodified insulin only in its more prolonged action in lowering the blood sugar, its administration and dosage should follow the same principles that govern the use of insulin in general; however, lente insulin is not adaptable for use in place of unmodified insulin in dealing with diabetic emergencies that require immediate-acting intravenous insulin. (Also see New and Nonofficial Remedies 1955, under the general statement on insulin.)

Dosage.—Lente insulin is administered as a buffered suspension by deep subcutaneous injection. It should not be injected into underlying muscle and is never administered intravenously. The container vial should be rotated and inverted several times to insure uniform distribution of the suspended particles, but vigorous shaking and frothing should be avoided. The potency is expressed in terms of insulin units per cubic centimeter of suspension. The number and size of daily doses, time of administration, diet, and exercise must be determined by careful observation under laboratory control, with frequent blood sugar estimations and urinary sugar examinations in each individual case. Usually the most satisfactory time for injection is in the morning before breakfast. In newly developed, uncomplicated cases of average severity, an initial daily dose of 10 units may be administered before breakfast; this may then be increased by 3 to 5 units until proper control of blood and urinary sugar is achieved. In patients already under treatment with protamine zinc insulin or unmodified insulin or both, a beginning dose of lente insulin of approximately 20% fewer units may be substituted; this is then increased if necessary. Patients on isophane insulin may be transferred directly to lente insulin on a unit-for-unit basis. In certain severe cases, further regulation of diet may be important to obtain the optimum dosage level. As with protamine zinc insulin, the proportional distribution of food of one-fifth, two-fifths, and two-fifths respectively for the three meals may be advantageous. Afternoon and bedtime feedings may become desirable or necessary in some circumstances at the discretion of the physician.

Suspensions of lente insulin should be stored in a cold place, preferably a refrigerator. Exposure to freezing or high temperatures should be avoided. Vials in use also should be protected from strong light and the contents used as continuously as possible. A partially empty vial not used for several weeks should be discarded. A vial in which the precipitated suspension has become clumped or deposited on the wall of the container should not be used.

Eli Lilly & Company cooperated by furnishing scientific data to aid in the evaluation of lente insulin.

Hydrabamine Penicillin G.—Hydrabamine penicillin G is a mixture of crystalline penicillin G salts consisting chiefly of the salt of N,N'-bis-(dehydroabietyl)ethylenediamine, with smaller amounts of the salts of the dihydro- and tetrahydro-derivatives. The structural formula of hydrabamine penicillin G may be represented as follows:



Actions and Uses.—Hydrabamine penicillin G, a water-insoluble dipenicillin compound salt of a rosin amine base, is useful in the treatment and prevention of penicillin-susceptible infections. (See New and Nonofficial Remedies 1955, under the general statement on penicillin.) Its prophylactic use should be limited to streptococcic and pneumococcic infections of the throat and ears, to procedures such as tonsillectomy and dental extractions, and to patients with a history of rheumatic fever or rheumatic heart disease. As with other penicillin compounds, it is of no value for the treatment or prevention of the common cold or influenza.

Given orally, hydrabamine penicillin G promptly produces satisfactory penicillin blood levels when administered in doses of 300,000 to 600,000 units at 6 hour intervals. After 6 hours, the blood level produced by similar single oral doses falls rapidly. The onset of the maximum blood level produced by single oral doses is only slightly delayed when administered with meals, and the height and duration of the blood level is not affected appreciably by digestive function. Median blood levels obtained following oral administration of 600,000 unit doses are approximately twice those obtained with 300,000 unit doses. Animal studies indicate that the hydrabamine base portion of the compound is chiefly unabsorbed when given by the oral route; up to 90% is recovered in the feces with less than 1% found in the urine. Fecal excretion of the base is not significantly influenced by the normal intestinal flora.

Hydrabamine penicillin G has about the same toxicity in animals as benzathine penicillin G. Chronic toxicity studies in animals with doses far in excess of those recommended for human beings have not disclosed hematological or other abnormalities. Clinically, looseness of stools has been observed as a rare side-effect and urticaria has been attributed to the drug. Physicians should be alert to the possibility of allergic reactions, stomatitis, or monilial infection of the gastrointestinal tract. As with other penicillin compounds, allergic reactions may be controlled with antihistamine medication, but when this fails or when there are monilial complications, the drug should be discontinued.

Dosage.—Hydrabamine penicillin G is administered orally for acute infections in initial doses of 300,000 to 600,000 units every 6 hours for adults; subsequent dosage should be regulated according to the therapeutic response. In children, oral doses of 300,000 to 600,000 units four times daily may be adequate. To maintain continuous prophylaxis in rheumatic fever, approximately 300,000 units orally once or twice daily is suggested; patients with streptococcic infections who have had rheumatic fever or show signs of rheumatic heart disease should receive a total of 800,000 to 1,200,000 units per day (a smaller amount for children, larger for adults) in four divided doses for the first 5 days, and 600,000 to 750,000 units per day in three divided doses for the second 5 days. The entire 10 day treatment should be administered to such patients even though fever or symptoms disappear before the end of this period.

Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of hydrabamine penicillin G.

ECONOMICS OF MEDICAL CARE SINCE 1929

Elsewhere in this issue (page 41) is the first part of a two-part review of the economic position of medical care over the past quarter century by the A. M. A. Bureau of Medical Economic Research. The findings emphasize the "middle ground" position of the medical care "industry" during that period, 1929-1953, when gross national product rose from 104 billion to 365 billion dollars and personal consumer expenditures rose from 79 billion to 230 billion dollars. While dollars expended for medical care followed the over-all pattern of expansion, the Bureau notes that since 1930 the percentage of personal consumer expenditures going for medical care varied only slightly, from 3.99 to 4.35. Since World War II, however, the percentage has risen at a more rapid rate, from 4.14 to 4.35.

One factor that increased personal consumer expenditures for medical care, in dollars and as a percentage of the total, was the tremendous upswing since World War II in the number of births and the birth rate. The increased number of babies and young children has affected not only hospital and obstetric expenditures but has increased the demand for other medical services, since this youngest age group normally requires the most frequent medical attention. In the long run, of course, this imbalance will be corrected as today's toddlers become tomorrow's productive adults. Moreover, the reduction of the maternal mortality rate to a very low level has contributed to the high birth rate by reducing the mortal fear of childbearing almost to the vanishing point. The economic effect of the 1,200,000 increase in births from 1945 to 1953 has been obscured by statistics that do not show a division of medical expenditures into those for childbearing, disease, and accidents. Without such a breakdown, it is easy to misinterpret the increase in medical expenditures by ascribing it to a decline in the health of the American people or a disproportionate rise in medical care costs. The Bureau study has isolated as a second factor responsible for the increase in expenditures the item "medical care and hospitalization insurance." These expenditures represent premiums less claims paid; this difference is primarily overhead cost. The rapid growth in voluntary health insurance has resulted in an increase of 779 million dollars in this insurance overhead item from 1929 to 1953; this amount represents one-ninth of the total 7,064 million dollar increase for all medical care items. The increase in overhead costs is, of course, a price that must be paid for the rapid extension of voluntary health insurance.

Turning from expenditures to prices, the Bureau notes that the index for medical care and drug prices, as indicated by the U. S. Bureau of Labor Statistics' Consumer Price Index, (1935-1939 equal 100), stood at 173.9 in 1954—well below the 191.9 for the entire Index. The item indexes for physicians' and dentists' fees were still lower—160.3 and 174.5. The only component of the total medical care and drug index that showed a marked rise was hospital room rates, which was 322.1 in 1954; if the upward effect of this component were eliminated, the over-all medical care and drug index would be still lower. Newspaper releases about monthly changes in the cost of living usually refer to indexes based on the period 1947-1949 equal 100. This study points out that the new base indexes for some items, such as men's street shoes and women's cotton house dresses falsely imply that the prices of these items have not risen very high, whereas the true explanation is that they attained a very high level before 1949. Other items, such as rent and medical care, appear to be high priced because their price rise came so late in this 15-year period of inflation. However, this does not deny that the indexes for the medical and hospital items have risen more rapidly since 1949 than the entire Consumer Price Index.

A dollar spent for medical care in 1953 was not divided among the suppliers of these services and commodities in the same way as was a 1929 dollar. The 33 cents that the physician received in 1929 dwindled to 28 cents by 1953; the share of the dentist and that for drugs and sundries also declined. The compensatory increases were for all other medical care (which includes the rapidly growing insurance overhead item) from 17 to 20 cents; and for hospitals, from 14 to 26 cents. If these trends continue, the hospitals' share will exceed the physicians' share by 1960. The sharp rise in productivity, or output per physician, has counterbalanced the lag in physicians' fees and the decline in the physicians' share of the medical care dollar. Thus, the effective supply of physicians' services has increased much more rapidly than the number of physicians. Also, seeing a decreasing percentage of patients in their homes has resulted in a saving of the physician's time. Use of more auxiliary personnel in his office and in the hospital and use of more effective drugs have also been major factors in increasing the technological efficiency of the physician. As a result, the average income of physicians rose at almost exactly the same rate as the average earnings of all wage and salary workers over the period. From 1929 to 1949 the percentage rise was 108 compared to 109; and for 1949 to 1951, 13 compared to 15. Estimates indicate no change in this trend since 1951. The incomes of physicians and their patients continue to keep pace.

The various providers of services and commodities in the medical care "industry" can well be proud of a quarter century record that included great medical advances—the increased life expectancy at birth, the declines in infant and maternal mortality, and the development of new drugs and treatments—while little change occurred in the industry's relative economic position. Possibly this is our most efficient industry!

COMPONENT MEDICAL SOCIETIES

The American Medical Association Bureau of Medical Economic Research has recently published the results of a statistical survey of the 1,929 component medical societies in the 48 states. This 81-page study, known as Miscellaneous Bureau Publication M-95, "Component Medical Societies: Membership and Boundaries," is a compilation and interpretation of information furnished by the executive secretaries of the state medical associations. It includes a 72-page list by state of the name of the component society, the name or names of the counties included, the number of counties, and the membership; the summary at the end of each state list includes a membership array in descending order, the names (if any) of the unorganized and inactive counties, the total number of counties in the state, and the number of component societies. Membership of the component societies in 1954 totaled 156,598. This number should not be confused with the total membership of the state associations because of the variations in membership rules of the component societies; for example, the retired members in some component societies are not members of the state associations but continue to be members of their component societies. One-third (52,157) of this total membership was accounted for by the 24 largest component societies, each of which had more than 1,000 members in 1954; the 244 societies that had between 100 and 1,000 members had a total of 63,997, or 40.9% of the total; the remaining 40,444 members, or 25.8% of the grand total, were distributed among the 1,661 societies comprised of less than 100 members. There were 209 societies with 50 to 99 members; 102 societies had 40 to 49 members; 161 had 30 to 39; 253 had 20 to 29; 534 had 10 to 19; and 402 had fewer than 10 members. More specifically, 127 societies had less than five members and 275 societies had from five to nine members. The purpose of this compilation is not to discount the importance and need for component societies with few members.

A county outline map of the United States with four shaded patterns is a part of the Bureau publication. Shaded patterns indicate that 1,526 of the component societies cover just one county or less, 176 societies cover 2 counties, 154 societies cover more than 2 counties but fewer than 5, 64 societies cover 5 to 10 counties, and 7 cover 11 or 12 counties. At the extreme are two component societies—one in Mississippi and one in Virginia—that cover 13 counties each; 158 counties are unorganized, and 11 counties are inactive. There is a component society for each county in only seven states—Alabama, Arizona, Connecticut, Delaware, New Hampshire, New Jersey, and Ohio. At the other extreme are only three states with no single county society—Nevada, North Dakota, and South Dakota. The geographical patterns of these component societies along with the membership data may profitably be compared with the 757 medical service areas shown in Bureau Bulletin 94, "Distribution of Physicians by Medical Service Areas," and Bulletin 94A, "Map Supplement to Bulletin 94." The latter reflect the trading area principle, whereas the boundaries of component societies are political and were established many years ago. Although it would be outside the scope of any Bureau publication to urge a regrouping of component medical societies, comparisons with the 757 medical service areas and the data in this new Bureau publication will provide the officers of our constituent associations and component societies with a considerable amount of basic information for other states.

ESTABLISHING NEW PRACTICES

The physician seeking to take advantage of opportunities made possible by our growing suburban and small-city populations faces the problem of reconciling the financial obstacles with his professional and community-service goals. Local financing through banks and supply company credit often fall short of the working capital needs of a new practice, particularly for the young physician who lacks managerial "know-how." The American Medical Association and other organizations have stimulated communities seeking young physicians to offer personal and professional advantages such as a home or office facilities. Much progress has been made through these activities, but the financial problem is less easily tackled and solved. It poses further complications —that of aiding the physician but avoiding a "handout," and that of getting him started without putting him under obligations that may hamper his freedom in the practice of medicine. The Sears-Roebuck Foundation, with the cooperation and guidance of the A. M. A., has launched a program of assistance designed to encourage new medical practice units and improve medical care without threatening medical autonomy.

The foundation's Plan of Assistance (see this issue, page 38) will provide long-term, low-cost unsecured loans of up to $25,000 to physicians seeking to establish medical practice units. It requires that the physician first exhaust all local possibilities for financing, that his application indicate a need for a practice in the proposed locality and good possibilities for success and public service, and, that it give evidence of effort and thought in planning a well-organized, effective practice unit. Contributions made by the grantee in repaying the grant will be turned back into the fund for the establishment of further practices, thus providing what the foundation calls "built-in chain reaction." The plan also features advantages encouraging early repayment of grants to speed up establishment of more practices.

The foundation states that its plan is intended to "realize the principles of opportunity, incentive, mutual help and self reliance; to give the American people the best possible medical care; and to help the American physician build for himself the most effective, the most rewarding and the most satisfying life as a professional man." Continuation of the plan after 1955 depends on its reception and support by the medical profession. The plan relies on individual initiative and enterprise, requires that assistance be given only where it will generate independence, and is sustained entirely by those who benefit from it. As a proof that free medicine and free industry can solve medicoeconomic problems in a practical but optimistic way, it deserves support. As a proof that there are means of improving medical care without compromising medical self-reliance, it demands support.

ORGANIZATION SECTION

"NEW PRACTICE" ASSISTANCE GRANTS OFFERED

The Sears-Roebuck Foundation, in cooperation with the American Medical Association, has announced a new Plan for Assistance in establishing medical practice units with loans of up to $25,000, beginning in 1955. The unsecured, low-cost, 10-year loans will be available to physicians seeking to establish new practices but unable to arrange full local financing. The loans, intended especially for small or medium-size towns, growing suburbs, or rural communities, will be offered to physicians in at least one location in each of five regions covering the United States. Applications will be screened by a medical advisory board selected from A. M. A. Board of Trustees nominations. Investigations and the physician's application will provide the advisory board with information on these questions: Is the proposed location of the unit logical? What will it bring to its community? What is its chance of success? How much initiative has the applicant?

Under the terms of the note, payments of $12 a month per $1,000 borrowed are due after three years and must continue until repayment is complete. Accelerated payments may be made. Recipients also must pledge themselves to make a $240 tax-free contribution to the Sears-Roebuck Foundation for each $1,000 borrowed. Payments may be made at any time but must begin after the fifth year, at a rate of $2 per month per $1,000 for the fifth year; $3 a month for the sixth and seventh years, and $4 a month for the last three years. All money returned to the foundation will be used to help establish new practices. Two features are planned to encourage early repayment, so that these additional grants may be made: 1. As long as no repayments are being made on the principal—up to three years—interest at the rate of 6% per year ($5 a month per $1,000) is charged. Interest is canceled as soon as repayments begin. 2. All pledges are to be spread over the last six years of the term, but those not yet due will be canceled if the grant is repaid before 10 years. Grantees also must be covered by decreasing term life insurance with any insurance company for the amount of their grants excluding pledges.

Further information may be secured from the physician's placement office of the nearest state medical society, or from the Council on Medical Service, American Medical Association, 535 N. Dearborn, Chicago. Applications must be sent to the Director, Sears-Roebuck Board, in the region where the proposed practice would be located. The regional addresses are: Pacific Coast—2650 Olympia Blvd., Los Angeles 54; Southwest—1409 S. Lamar St., Dallas 2; Midwest—8 E. Congress St., Chicago 5; South—675 Ponce de Leon Ave., Atlanta, Ga.; East—4640 Roosevelt Blvd., Philadelphia 32.

This plan was formulated by the recently created medical advisory board of the foundation. The board is headed by Dr. F. J. L. Blasingame, Wharton, Texas, chairman, and Dr. Edwin S. Hamilton, Kankakee, Ill., vice-chairman, who, together with Dr. James R. McVay, Kansas City, Mo., are members at large. Regional members are Drs. Samuel P. Newman, Denver, Midwest; James Z. Appel, Lancaster, Pa., East; David Henry Poer, Atlanta, Ga., South; Eugene F. Hoffman, Los Angeles, Pacific Coast; Robert D. Moreton, Fort Worth, Texas, Southwest; Drs. J. A. Bargen, Rochester, Minn.; Lawrence R. Dame, Greenfield, Mass.; J. P. Culpepper, Hattiesburg, Miss.; Raymond M. McKeown, Marshfield, Ore.; and Alfred R. Sugg, Ada, Okla. Ex-officio members are Drs. Elmer Hess, Erie, Pa., A. M. A. President; Gunnar Gundersen, LaCrosse, Wis., Chairman of the Board of Trustees; and Dwight H. Murray, Napa, Calif., President-Elect.

SYMPOSIUM ON HEALTH HAZARDS OF CHEMICALS

The A. M. A. Committee on Toxicology and the Committee on Pesticides will sponsor a symposium on the health hazards of chemicals in the home, agriculture, and industry during the annual meeting of the American Association for the Advancement of Science. The symposium will be held before the section on pharmacy, Dec. 29 in the Henry Grady Hotel, Atlanta, Ga. There are about 25,000,000 chemical products now available for use in the three fields to be discussed, and it is estimated that 3,300 deaths occur annually from misuse of chemicals. The committees have gathered a panel of experts to discuss the problem before scientists from many fields. Bernard Conley, Secretary of the A. M. A. Committee on Pesticides, will be moderator. The symposium members will include Dr. Lester M. Petrie, director of the preventable disease service, Georgia Department of Health, Atlanta, Ga.; Dr. Wayland J. Hayes, chief, toxicology section, Communicable Diseases Center, U. S. Public Health Service, Savannah, Ga.; Dr. Irvin Kerland, associate medical director, federal Food and Drug Administration, Washington, D. C.; and Mrs. Veronica Conley, Assistant Secretary, A. M. A. Committee on Cosmetics.

A STUDY OF MULTIPLE SCREENING

The Council on Medical Service of the A. M. A. has just revised its pamphlet on multiple screening. The present report includes descriptions of 33 multiple surveys in 14 states and the District of Columbia, ranging from small surveys in a single company to statewide projects. Costs and results have been given when such information was available. Copies can be had by writing to the Council on Medical Service, 535 N. Dearborn St., Chicago 10.

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Military Dependents' Medical Care

Senators Russell (D., Ga.) and Saltonstall (R., Mass.), in S. 2720, and Congressman Vincent (D., Ga.), in H. R. 7792, introduced the administration's proposal "to provide medical care for dependents of members of the Armed Forces of the United States." This replaces S. 934 and H. R. 2685 previously reported. The legislation follows the basic recommendations of the 1953 Molton committee and would authorize medical care for dependents of the members of the armed services. "(*a*) in military medical facilities subject to the availability of space, facilities, and capabilities of the medical staff; (*b*) through an insurance plan . . . and (*c*) from civilian medical sources . . . for dependents of members of the Armed Forces not participating in an insurance plan. . . . Provided that no military medical facilities are available for such dependents." The measure specifically states that: "The medical care of dependents of members of the Armed Forces provided for in military medical facilities shall in no way interfere with the primary mission of the military medical services to provide proper medical care for military personnel. The Secretary of Defense may establish charges for any subsistence given dependents of members of the Armed Forces in connection with medical care in military facilities. (*c*) As a restraint on excessive demands for medical attention in military medical facilities, additional charges may be imposed for out-patient care but such charges shall be limited to such amount, if any, as may be established by the Secretary of Defense pursuant to a special finding that such charges are necessary. . . ."

"Sec. 5. The Secretary of Defense is authorized to contract for the medical care, under the provisions of this Act, of dependents of members of the Armed Forces, under such private insurance plan or plans as he shall deem appropriate, subject to the following limitations: (*a*) Members of the Armed Forces shall be entitled to participate in such plan or plans upon filing of an application to participate on forms provided by the Department of Defense. (*b*) The cost of each private insurance contract shall be apportioned between the member of the Armed Forces and the Government. The contribution by the member of the Armed Forces shall not exceed 30 per centum of the monthly cost and not to exceed $3 per month estimated at the time of his filing of a request to participate in such a plan. (*c*) Members of the Armed Forces may select such optional coverage as such plan shall provide. (*d*) Payment by a member of the Armed Forces of his share of the cost of the premium of such private insurance contract shall be by allotment of pay as the Secretary of Defense shall prescribe. (*e*) Such private insurance plan shall not provide for any limitation on periods of authorized medical care for dependents of members of the Armed Forces for each accident or illness. (*f*) The Secretary of Defense, in contracting for such insurance plan or plans, shall provide for a reduction of the costs to the extent that dependents of members of the Armed Forces participating in such plan are cared for in military medical facilities. (*g*) The charges for medical care rendered under such private insurance plan by civilian physicians and surgeons and hospitals and treatment facilities under civilian control shall not be at rates in excess of the physician's, surgeon's, hospital's, or treatment facility's standard schedule of charges for semiprivate accommodations to the general public or to group-insurance patients (whichever is lower) for the services rendered.

"Sec. 6. Dependents of members of the Armed Forces who do not elect to participate in an insurance plan as authorized under section 5 of this Act and who are in need of medical care, for which military medical facilities are not available, because of inaccessibility, lack of space, facilities, or capabilities of the medical staff, are authorized to receive medical care as provided in this section for duly licensed physicians and facilities under civilian control. However, no funds shall be expended for professional service except in accordance with schedules of maximum fees and costs for such professional service established by the Secretary of Defense. He may consult with accredited medical associations and any other agencies which he considers appropriate. The payment for services rendered by hospitals and clinics shall be at rates not in excess of the hospital's or clinic's standard schedule of charges for semiprivate accommodiations to the general public or to group-insurance patients, whichever is lower, for the service rendered. As a restraint on excessive demands for medical care, dependents receiving medical care in civilian medical facilities, under the terms of this section, shall be required to pay 30 per centum of the first $100 plus 15 per centum of the cost of the remainder of inpatient care and 30 per centum of the cost of outpatient care. However, in cases of protracted periods of illness or other hardship cases, the Secretary of Defense may provide for the transfer of such dependent to a military facility or take such other appropriate action to alleviate such hardship.

"Sec. 7. As used in this Act—(*a*) The term 'member of the Armed Forces' includes—(1) a person, appointed or enlisted in, or inducted, called or conscripted into, the Army, Navy, Air Force, or Marine Corps, or members of the reserve components who have entered on extended active duty in excess of ninety days but not including persons on duty for training purposes only; and (2) a member or former member of the Army, Navy, Air Force, or Marine Corps, who is entitled to retirement . . . other than those entitled to receive retired or retirement pay [as members of the Reserve]" and those nonregular officers of the Army, Navy, and Marine Corps placed on the emergency retired list under the act of May 24, 1928, as amended, by reason of disability incurred in World War I and their dependents who are furnished medical care by the Veterans Administration.

"(*b*) The term 'dependent' includes—(1) in the case of any male member—(A) his lawful wife; (B) his unmarried dependent children. The term 'children' shall in addition to the members' own or lawfully adopted children include stepchildren, or such other children as depend upon the member for support and live with the member in a regular child-parent relationship; children shall not be included in the term 'dependent' who are over the age of twenty-one years, except such children who are incapable of self-support because of being mentally or physically incapacitated and who are in fact dependent on the member for over half of their support; (C) his parents and parents-in-law if in fact dependent on him for over half of their support; and (2) in the case of any female member—(A) her lawful husband, if in fact dependent on her for over half of his support; (B) her unmarried dependent children. The term 'children' shall in addition to the members' own or lawfully adopted children include stepchildren, or such other children as depend upon the member for support and live with the member in a regular child-parent relationship; children shall not be included in the term 'dependent' who are over the age of twenty-one years, except such children who are incapable of self-support because of being mentally or physically incapacitated and who are in fact dependent on the member for over half of their support; (C) her parents and parents-in-law if in fact dependent on her for over half of their support; and (3) unmarried widows and the dependent children of persons who were members of the Armed Forces, as defined in this Act, at the time of death are authorized medical care under the terms of this Act.

"Sec. 8. Medical care under this Act shall be limited to the following: (*a*) Diagnosis; (*b*) Treatment of acute and medical and surgical conditions; (*c*) Treatment of contagious diseases; (*d*) Immunization; and (*e*) Maternity and infant care.

"Sec. 9. Hospitalization shall not be authorized dependents of members of the Armed Forces for the following: (*a*) Domiciliary care and chronic diseases; (*b*) Nervous and mental disorders (except for diagnostic purposes); and (*c*) Elective medical and surgical treatments as determined by the cognizant physician.

"Sec. 10. (*a*) Dependents of members of the Armed Forces shall not be provided prosthetic devices, hearing aids, orthopedic footwear, and spectacles, except that outside the continental limits of the United States and at remote stations within the continental limits of the United States where adequate civilian facilities are not available, those items, if available from military stocks, may be provided to dependents at prices representing full cost to the Government. (*b*) Dependents of members of the Armed Forces shall not be provided—(1) ambulance service,

---

From the Washington Office of the American Medical Association.

except in acute emergency, and (2) home calls except in special cases where it is determined by the cognizant physician to be medically necessary.

"Sec. 11. Except outside the continental limits of the United States and in remote areas within the continental limits of the United States where adequate civilian dental facilities are not available, *dental treatment* for dependents of members of the Armed Forces will be restricted to emergency dental care and dental care as a necessary adjunct to medical or surgical treatment. Emergency dental care is defined as the care required to relieve pain and suffering and shall not include any permanent restorative work or dental prosthesis. Dental treatment which may be provided dependents of members of the Armed Forces under this section will be obtained in military dental facilities and will depend upon the availability of space, facilities, and capabilities of the dental staff. Dependents of members of the Armed Forces are not authorized dental care at government expense through civilian dental sources, except as a necessary adjunct to inpatient medical or surgical treatment."

The Assistant Secretary of Defense in transmitting the legislation to Congress said that further technical improvements "in all probability may be proposed such for example, as the coverage of widows and the dependents of decreased military personnel and the extent to which military personnel may be authorized on their own option to move in and out of insured status." The annual cost for 2,204,500 dependents as of Dec. 31, 1954, would be 76 million dollars. These measures were referred to the Committee on Armed Services.

Federal Employees Contributory Health Insurance

Senator Johnston (D., S. C.) and Senator Carlson (R., Kan.), in S. 2425, and Congressman Rees (R., Kan.), in H. R. 7241, have introduced the administration's proposal for voluntary contributory health insurance for federal civilian employees. The employee would have the choice of two types of coverage: local nonprofit plans furnishing health services, employee-sponsored plans, or indemnity plans, providing 75% of the employees in the particular operation enroll in such a plan (Blue Cross and Blue Shield could qualify in this category); or a uniform national indemnity plan contracted for by the Civil Service Commission.

The federal government's contract in either plan would be limited to one-third of the premium of $52 a year for employees with dependents, or $19.50 for single employees, whichever is less. Under the uniform plan the cost to a single employee could not exceed $39 a year, and for an employee with dependents the cost could not exceed $104 a year. The uniform policy would provide daily board and room, with the benefit not to exceed $15 for each day of hospital confinement not exceeding 70 days. Additionally, $300 would be allowed for other hospital services and supplies. Maximum maternity benefits would be $125 for pregnancy in lieu of all other hospital benefits. Surgical benefits would be limited to $250. Major medical cost insurance would also be available with a $10,000 limit. The employees would have to meet the first $100 of expense after expiration of basic benefits before the major medical cost policy would become effective, after which they would be assessed 25% of the costs, with the policy paying a maximum 75% or $10,000, whichever is less. The Civil Service Commission would have the right to approve any participating insuring program and its health service benefits. An advisory board of 5 to 11 federal employees appointed by the chairman of the Civil Service Commission would advise policy. These measures were referred to the Committee on Post Office and Civil Service.

Veterans' Medical Care

Senator Smith (R., N. J.), in S. 2406, Senator McCarthy (R., Wis.), in S. 2483, and Congresswoman Church (R., Ill.), in H. R. 7355, have introduced identical measures to carry out part of the Hoover commission's recommendations on federal medical services. All appropriations for general hospitals for the Veterans Administration would be rescinded, except where construction has actually begun or where a contract has been executed. Authorization would also be rescinded if no appropriations have been made. The veterans' signed statement of inability to pay for hospital care for non-service-connected illness or disability would be subject to verification by the Veterans Administration and if found "not to be substantiated, such administration is authorized to collect the amount of the medical costs incurred, together with any amount paid in connection therewith for transportation of the veteran to and from the Veterans Administration facility, in such manner as the Administrator shall prescribe."

Veterans would be requested to assume an obligation to pay the cost without interest at some future date if they are financially able to do so. For hospital or domiciliary care for disease or disability not due to military service, the Veterans Administration would be "authorized to furnish out-patient treatment and care, prior to or following hospitalization, to any veteran of any war who was not dishonorably discharged, who is suffering from disability, disease or defect (not including neuropsychiatric ailments prior to hospitalization), who is in need of outpatient dispensary care, and who is unable to pay therefore, irrespective of whether the disability, disease, or defect was due to service. Any veteran who receives such out-patient treatment or care shall be required to assume an obligation for the future payment of the costs thereof," if the disease or injury was not service-connected. The Senate bills were referred to the Committee on Labor and Public Welfare; the House bills were referred to the Committee on Veterans' Affairs.

Federal Hospital Service Other Than Military

Senator Smith (R., N. J.), in S. 2407, Senator McCarthy (R., Wis.), in S. 2481, and Congresswoman Church (R., Ill.), in H. R. 7346, have introduced identical measures to carry out part of the recommendations of the Hoover commission Report on Federal Medical Services. Major provisions are: (1) American merchant seaman "shall no longer be entitled, in accordance with regulations, to medical, surgical, and dental treatment and hospitalization without charge at hospitals and other stations of the Public Health Service"; and (2) Coast Guard, the Coast and Geodetic Survey, and Public Health Service personnel would be provided medical, surgical, and dental treatment and hospital care only at the nearest available facilities of the military medical services. Medical advice, outpatient treatment, and hospitalization furnished to the dependents of the Coast Guard, Coast and Geodetic Survey, and Public Health Service would be "reimbursed by the agency whose personnel or dependents thereof received such treatment or hospitalization to the extent that such cost is not charged to the officer, enlisted person, or member of a crew concerned."

Medical, surgical, hospital services for the Bureau of Employees Compensation, supplied now at the Public Health Service institutions, would be provided in hospitals other than veterans, with costs reimbursed by the Department of Labor. As soon as practicable the surgeon general would close all veteran hospitals of the Public Health Service and all "other institutions, clinics, stations, and facilities thereof, except (1) those used for the care, detention, and treatment of narcotic addicts and persons afflicted with leprosy, mental illnesses, or tuberculosis, (2) facilities for the care of Indians, (3) Freedman's Hospital, (4) those used for research activities, including the National Institutes of Health, and (5) the clinics and other facilities necessary for making the medical examinations authorized for Federal employees and . . . for making the physical and mental examinations of aliens. . . . Any hospitals and other institutions, clinics, stations, or facilities which are closed as herein provided may be disposed of to the States or local communities or in such other manner as the Surgeon General may prescribe." The Senate measures were referred to the Committee on Labor and Public Welfare; the House measure was referred to the Interstate and Foreign Commerce Committee.

Mortgage Insurance for Nursing Homes

Congressman Priest (D., Tenn.), in H. R. 7608, would authorize federal mortgage loan insurance for construction of nursing homes both nonprofit and proprietary. The mortgage insured could not exceed 80% of the estimated value of the property. The reinsurance would not exceed 95% of the loan, and the loan could not exceed 30 years. The provisions are similar to those of Title II of the administration's omnibus health bill, S. 886 and H. R. 3458. This measure was referred to the Interstate and Foreign Commerce Committee.

BUREAU OF MEDICAL ECONOMIC RESEARCH

This survey of the economic position of medical care during a quarter century will be concluded in next week's issue of The Journal. *It will be reprinted, with additions, by the Bureau of Medical Economic Research as Bulletin 99; a copy may be obtained from the Bureau, 535 N. Dearborn, Chicago 10.*—Ed.

THE ECONOMIC POSITION OF MEDICAL CARE, 1929-1953

Frank G. Dickinson, Ph.D.
and
James Raymond, M.A., Chicago

The recent publication of "National Income," 1954 edition (a supplement to the *Survey of Current Business*), by the United States Department of Commerce warrants a review of the position of medical care in the American economy during the quarter century covered by the data in this new publication, 1929-1953. Previous publications of the Bureau of Medical Economic Research have summarized the national aggregates for medical care for the years 1929-1952. (A list of these Bureau publications by title is presented in Bureau publication M-90.) The new series makes minor changes for the earlier years and presents new data for 1953.

The American economy has undergone so many changes during the past quarter century that an attempt to treat medical care in isolation would be unsuccessful. Yet, even a reasonably satisfactory thumbnail sketch of the economic development of the United States is far beyond the scope of this article. We shall try instead to provide some answers to the following questions regarding the position of medical care in a changing economy: 1. What are some of the highlights in the expansion of the American economy during this quarter century? 2. What does the Department of Commerce mean by the term "personal consumer expenditures?" 3. What is the largest item of personal consumer expenditures? 4. What is meant by the term "personal consumer expenditures for medical care?" 5. How much was spent annually for medical care, 1929-1953, and how do these amounts compare with other expenditures and with total personal consumer expenditures? 6. How has the composition of the medical care dollar changed? 7. Have medical care prices since 1935 risen more rapidly or less rapidly than the prices of commodities and services widely purchased by consumers? 8. Have the average weekly wages of industrial workers risen less rapidly or more rapidly since 1935 than the cost of specified items of medical care? 9. Have the average incomes of physicians risen more rapidly or less rapidly than the average incomes of the gainfully employed? 10. Have the technological efficiency—"output per physician"—and improvements in the quality of medical care kept pace with comparable changes in other parts of the American economy?

Introduction

The 25-year period for which medical care costs are analyzed here is one-quarter of that century that may well go down as the hundred years of most rapid change in recorded civilization. The changes in medical care are an integral part of this vortex of change. The people have retained most of their freedom to make individual decisions as to which of the many desired material things or services they will place first, second, and third in their priorities. The purchase of medical care can, therefore, be discussed in meaningful fashion only in relation to other purchases. The kind of medical care that is now being purchased, in contrast to the medical care of 1929, can only be fully appreciated when considered along with other major changes in the pattern of consumer expenditure. Most of the significant changes, as assessed from the vantage point of the present, were not, of course, foreseen in 1929. Some very well qualified people prognosticated, in the year 1929, a maximum United States population of less than 150 million persons. Yet the tremendous, and wholly unanticipated, growth of the United States population since 1929 is probably the most outstanding feature of this quarter century (from 122 million to 158 million in 1953). Along with this great increase of 30% in population, there have been changes in the age composition. The number of people age 65 and over has increased by leaps and bounds. In the medical field this has meant the rise of a new specialty, geriatrics. It has also meant the development of many social and economic activities focused upon the elderly and/or retired person.

Linked to the increase in numbers of people have been two other changes of great significance: first, the increase in the proportion of the United States population living in urbanized areas and the concomitant increase in the numbers of these persons who are dispersed in the suburbs of metropolitan centers; and, second, the well-known developments in the amount and speed of all kinds of transportation, but especially the increase of 101% since 1929 in numbers of automobiles. Both of these linked developments were, of course, well under way in 1929. They were intimately tied up with the processes of specialization and centralization, characteristics not only of industry but also of the newer brand of agriculture. City boundaries burst at the edges, and population flowed into the outskirts. The suburb—with its white picket fences, its elementary schools, its shopping centers, and its physicians' and dentists' offices—came into full bloom. So marked was this outward thrust of city workers that it was necessary for the United States Bureau of Census to change its definition of "urban population"; 64% of the total population of the United States in 1950 was urban.

The development of diverse forms of transportation in this process of urbanization has profoundly affected the distribution of medical care. The great bulk of patients developed the habit of going to their personal physicians' offices, from where they were funneled, by the system of referrals, to the specialist in the adjacent office, to a nearby clinic, to a perhaps more distant hospital or to a great medical specialty center several air hours away. All of these developments have enabled the medical team of 1953 to handle more patients more successfully than was done in 1929.

ECONOMIC GROWTH

The most important economic events of the 25-year period are summarized rather well and very briefly by the United States Department of Commerce in its recent publication. "In broad outline this period embraces the following sequence of events: the precipitous fall from the prosperity of 1929 into the deep depression of the early nineteen-thirties; the subsequent recovery, interrupted by the brief recession of 1938, but then continuing through the remaining prewar years; the tremendous performance of the economy in the prosecution of World War II; reconversion and the postwar boom, with attendant inflationary strains; the mild business recession of 1949; and the rapid recovery of 1950, merging in the latter half of that year into the period of hostilities in Korea" (page 1).

The tremendous growth of the United States economy is reflected in the fact that gross national product (the nation's output of goods and services in terms of its total market value) rose from 104 billion dollars in 1929 to 365 billion dollars in 1953—an increase of 250%. From the consumer's standpoint there have been great changes in the make-up of this gross national product: the frozen food industry was born and grew to near maturity, home appliances not only increased but completely changed character, and sulfonamide drugs and the antibiotics (which have greatly aided the medical profession) were developed and exploited fully only during and after World War II. The inflation associated with World War II and with the Korean conflict resulted in the level of prices in 1953 being more than two-thirds above that of 1929. When allowances are made for this factor, the physical volume of the nation's output, as measured by the gross national product in constant prices, rose 105% over the period. This increase amounts to 57% in real

Regina Evans Holloman, research assistant, assisted in the preparation of the tables.

Because of space limitations table 5 and the appendix have been omitted and will appear in the Bureau's reprints.

output per capita. The growth results largely from the terrifically rapid rate of technological change and improvement that have made possible the gains in productivity per unit of measure. All domestic purchasing groups have shared in the increased volume of production. There has been a marked shift from private to government use of the nation's output; in 1929 government purchases of goods and services absorbed 8% of the gross national product, but in 1953 they took 23.5%.

Real product per man-hour was well over half again as large in 1953 as it was in 1929; this implies an average annual rate of increase somewhat greater than 2%. The product per physician-hour has increased; physicians are now treating more people and more successfully than they did in 1929. Apparently, the product per hospital-hour has increased. The average length of hospital stay has been significantly decreased, but there is often need of a platoon of personnel to participate in the treatment given to one person; e. g., the heart operation, the treatment of malignancies by radiation, the use of an artificial kidney, and many procedures unknown in 1929. Moreover, the tools or equipment used in hospitals are more numerous and diverse than they were 25 years ago, and some of them are quite expensive.

TABLE 1.—*Selected Personal Consumer Expenditures in the United States, 1929-1953 (Millions of Dollars)*

Year (1)	Total Medical Care (2)	Physicians' Services (3)	Hospitals (4)	Drugs and Sundries (5)	Dentists' Services (6)	All Other Medical Care (7)	Alcoholic Beverages (8)	Recreation (9)	Tobacco (10)	Personal Care (11)	Jewelry (12)	Total Columns (3)-(12) (13)	Total Consumer Expenditures (14)

Sources for tables 1-5: United States Department of Commerce, Office of Business Economics, National Income: A Supplement to the *Survey of Current Business*, 1954 edition; table 30, pp. 206-208, and personal correspondence with the Office of Business Economics. See also chart I.

The methods of estimation, reviewed in the appendix, are designed to exclude governmental and business expenditures for each item of personal consumer expenditures. Brief descriptions of the items (not the type of expenditure), arranged by column numbers, are presented below.

Because of rounding, some totals in this and other tables are not the sums of the individual entries.

(2) Total Medical Care: The sum of columns (3)-(7).

(3) Physicians' Services: Aggregate personal consumer expenditures are derived by the Office of Business Economics by multiplying (a) the number of physicians in independent practice (full or part time), by (b) their average gross income received from individuals (90% of total) as determined from questionnaire surveys of the profession. (Net income is three-fifths of their gross income.) Most of the income surveys used were conducted by the National Income Division. The estimates of number of physicians were adjusted for changing number of professional practitioners in the armed forces after 1940.

(4) Hospitals: This component consists of payments by patients to proprietary hospitals, and of current expenditures (including some depreciation) of nonprofit hospitals in providing care of patients.

(5) Drugs and Sundries: Expenditures include items not purchased in hospitals. Estimates for base years were based on manufacturing census and export and import statistics for selected items. Adjustments were made for the group of products for transportation costs, trade margins, taxes, and trade inventory changes. For other years estimates were based on extrapolation by retail sales series. Items include biological products, botanical drugs, medicinal chemicals, and pharmaceutical preparations; druggist and medical rubber sundries; clinical thermometers, hypodermic syringes and needles; surgical dressings; arch supports and other foot appliances; adhesive plaster, elastic stockings, elastic braces, suspensories, and other elastic supports; other surgical and orthopedic supplies and appliances; personal safety devices not elsewhere classified; and sanitary napkins and tampons.

(6) Dentists' Services: Estimates were derived by multiplying (a) the number of dentists in independent practice (adjusted for changing numbers in the armed forces after 1940), by (b) their average gross income received from individuals, determined from questionnaire surveys of the dental profession.

(7) All Other Medical Care: Included are (a) ophthalmic products and orthopedic appliances—field glasses; terrestrial and celestial telescopes; ophthalmic frames, mountings and parts; sun glass frames; ophthalmic focus lenses; sun or glare glasses and sun goggles; other ophthalmic goods; electric hearing aids; hearing aid batteries; artificial limbs (prosthetic); trusses and othopedic appliances (braces). Estimates are adjusted for such things as transportation costs and trade margins; (b) medical care and hospitalization insurance—premiums less claims: accident and health insurance, mutual accident and sick benefit associations, and gr [illegible] tions, administrative and medical expenses of [illegible] and students' fees for medical care; and (c [illegible] s—services of osteopathic physicians, chiropractors, chiropodists and pediatrists, private duty trained nurses, and the miscellaneous curative and healing professions. These estimates are, in the main, based on multiplication of the number of persons in independent practice by average gross income as established in questionnaire surveys. For the years for which such direct information is unavailable, extrapolation is for the most part based on income of physicians, which is felt to be parallel.

(8) Alcoholic Beverages: Includes distilled spirits, wine and beer, packaged form and by the drink.

(9) Recreation: See footnote to table 5, column (10).

(10) Tobacco: Includes all tobacco products, adjusted for tax-free and imported products.

(11) Personal Care: See footnote to table 5, column (4).

(12) Jewelry: Includes purchases of jewelry and watches.

Changes have also occurred in the flow of national income (the aggregate earnings of labor and property that arise from current production). There was a marked rise in the contribution of manufacturing industries, a 3% rise in the contribution of the wholesale and retail trade industries, and a decline in the percentage contributed by the agricultural sector. Significantly, the percentage of total national income contributed by government rose from 6% in 1929 to 11.5 in 1953; these two percentages represent only the labor directly employed by government and government enterprises. Moreover, the increase was almost entirely in the federal government component. An item of outstanding importance in the employee's share of national income is that of wage and salary supplements; they were an inconsequential element in 1929, but in 1953 they were 3.5% of national income. This growth represents the rise and expansion of the various insurance programs and of private pension, health, and welfare funds. Unfortunately, much of the increase in the total of personal income (current income received by persons from all sources) has been absorbed by direct personal taxes. These taxes, which were 3% in 1929, increased to 12.5% of personal income in 1953. Taxes, in dollars, are now 14 times as large as they were in 1929, and this relative increase is entirely in the federal government component. After deducting these taxes, there remained a total disposable personal income in 1953 of 250 billion dollars as compared with 83 billion dollars in 1929; with consumer prices averaging 59% higher in 1953 than in 1929, this increase in real disposable income per capita amounts to only about 45%.

Another important change was in personal consumer expenditures (the market value of goods and services purchased by individuals and nonprofit institutions); expressed as a percentage of the gross national product, they declined from 75.5% in 1929 to 63% in 1953. Nonetheless, the absolute volume of goods and services purchased for personal consumption was vastly increased, with a gain of over two-fifths in real consumption per capita. Gains in consumption per capita were, of course, commonplace prior to 1929. There have been marked shifts in consumption patterns that reflect, in part, differential movements of prices. They also reflect changes in the pattern of spending for commodities; i. e., the social compulsions that dictate at least one automobile per household, the greatly altered pattern of food buying. Just as disposable personal income excludes the amount paid out in personal taxes, personal consumer expenditures exclude all governmental expenditures; for example, personal consumer expenditures for medical care excludes governmental (and business) expenditures for medical care. In the last quarter century there has been little change in total personal medical care expenditures as a percentage of gross national product, of national income, or of personal income. As the following dollar aggregates and (rounded) percentages indicate, the total personal medical care expenditures as a percentage of disposable personal income have increased, however, by 0.5 of a percentage point, and as a percentage of personal consumer expenditures, by 0.7 of a percentage point; since 1930, the increases were only 0.2 and 0.3 points. (A table, showing these

	1929		1953	
	Millions (1)	Personal Medical Care Expenditures as % of Column (1) (2)	Millions (3)	Personal Medical Care Expenditures as % of Column (3) (4)

and other relationships for all of the 25 years, appears in the appendix.) The growth of the United States economy and inflation have made the smallest of these five national economic aggregates in dollars for 1953 more than twice the size of the largest aggregate for 1929.

PRIVATE VERSUS PUBLIC ECONOMY

National income and outgo aggregates, in turn, are only parts of the picture of a changing economy. They provide measures of the functioning of the economy, but not changes in what might be loosely termed the structure of the economy from the standpoint of those who own the material things. Students and teachers of economics usually recognize the basic shortcoming of the "income approach" to the study of economics, in this case, medical economics. This major shortcoming can be explained in a simple manner by an analogy. Could the United States Steel Corporation, the American Telephone and Telegraph Company, or any other large national organization run its affairs by depending solely upon an income and outgo summary of its business operations? Obviously the net results of a year or a quarter's operation must be incorporated into the statement of assets and liabilities before the managers and stockholders of the corporation can measure the operating results and plan for the future.

The limited balance sheet presented by the Department of Commerce as a summary of the operations of the American economy is interesting and helpful, but this limited approach is outside the scope of the present discussion. The point must be made and made quickly, however, that the increase in real disposable income per capita of about 45% during this quarter century is an incomplete and misleading measure of the economic progress attained. This particular measure must be examined against a broader background, against the changes in the balance sheet of the American economy during this quarter century. The (gross) federal debt has risen by leaps and bounds, from 18 billion dollars in 1929 to 289 billion in 1953, excluding the large contingent liability under guaranteed mortgages and other programs. (Including state and local government debt, the increase has been from 35 billion to 322 billion dollars.) The full impact of this increasing indebtedness cannot be eliminated from this running account of changes in the American economy by pushing aside the increase in the federal debt with the statement that "we owe it to ourselves," even if the stress is on the second instead of the last word. When a family head considers his wealth or net worth he deducts the amount of the mortgage on his home and on his business properties but he counts among his assets the amount of government bonds that he owns and makes no deduction for the amount of the government bonds that he and his children owe. Consequently the typical householder in 1953 thought he was a lot richer than he really was. This elusive influence of the public debt makes the American people collectively think they are at least 289 billion dollars richer than they really are. In measuring the economic growth of our national economy for this quarter century of time we must, if we wish to be realistic, recognize the rise in the public debt as one of the unfortunate characteristics of the period. It is not necessary to engage in a controversy with Keynesian economists or other inflationists to demonstrate the simple truth that this 45% gain in disposable income per capita was attained during a quarter century when the illusion of great wealth was being created by a tremendous rise in the national debt. In other words, the accomplishment of this 45% gain would have been far greater if the public debt had not expanded.

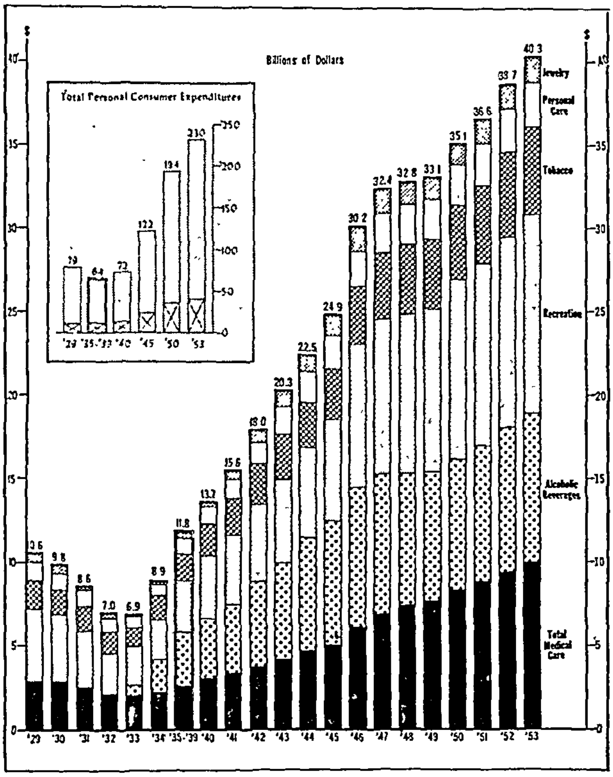

Chart I.—Selected personal consumer expenditures in the United States, 1929-1953. Source: *Survey of Current Business,* 1954 National Income Supplement.

Another liability of a somewhat similar nature that grew up in this quarter century was the deficit in the Old-Age and Survivors Insurance Trust Fund. The amount of the deficit depends upon the assumptions as to such factors as interest rates, mortality rates, and probability of remarriage. This implied obligation of the sovereign power to pay pensions to millions of gainfully employed persons while charging them cut-rate premiums has created a liability for succeeding generations that is almost as real as the liability created by the rising public debt. This additional liability of the government, which is not generally recognized as a liability by heads of families, was at least 200 billion dollars in 1953. It is another "deficit" item that must be considered in measuring the net gains in the nation's economy during the quarter century; at least, in the interpretation of these net gains. It must be added to the public debt; the people collectively think they are almost 500 billion dollars richer than they really are. The complete picture cannot be presented by merely calling attention, as we have, to the increasing role of government, from 8% to 23.5%, in these annual national aggregates. These deficits, while creating an illusion of great wealth, have placed our economy on a treadmill. How to keep this treadmill from slowing down is obviously not one of the questions to be answered in this discussion.

Moreover, difficulties involved in combining private and public items affect the choice of a frame of reference for considering the economic position of medical care during the quarter century. Basically, this is a problem of economic perspective. Consider food, the largest item in personal consumer expenditures. So long as the discussion is restricted to personal consumer expenditures—what we spend as individuals, not what we spend as individuals and taxpayers—the food item seems reasonably clear. But an attempt to include public expenditures for food raises a number of interesting questions. Should the expenditures of the federal government for soil conservation and other forms of subsidy for farmers be added to the food item in estimating the public plus the private expenditures for food? The answer to such a question is very involved. Our purpose is merely to raise the question in order to pinpoint the pitfall of considering the need for medical care as the only human need, because the consideration of one human need can give rise to all manner of special pleading. People literally need everything, and focusing too much attention on one human need at a time is an unscientific procedure as well as one that can lead to many false conclusions.

Source: Table 1. See also chart II.

If the purpose were merely to divide people into two categories, the well and the sick, it would be necessary to consider the sick people who were taken care of by government. In our study of the age and sex distribution of hospital patients (Bulletin 97) equal attention was given to patients in public and private hospitals. But for the purpose at hand this simple procedure would be highly misleading because we are discussing dollar expenditures; we are discussing national economic aggregates. Our larger frame of reference must be the wealth and income of the American people, as the task at hand is more economic than medical. This vital distinction is often overlooked.[1] The dilemma may be sharpened by considering a few items. Should the expenditures of the United States Department of Defense for the medical care of defense personnel be considered as a public expenditure for medical care? Should the expenditures of the Veterans Administration for the care of veterans with service-connected disabilities be considered a public expenditure for medical care? Doubtless most economists would consider both expenditures better classified if they were treated as defense expenditures for past, present, and future wars. The use of a frame of reference for defining the economic position of medical care that involves an allocation of these public expenditures to medical care items would merely call attention to the fact that we have had several wars recently. Should expenditures of employers for the medical care of injured workmen be considered as medical care expenditures or as among the costs of operating business enterprises? One of the virtues of using personal consumer expenditures as a frame of reference is that it excludes such items as the medical expenditures of the armed forces, of the Veterans Administration, and for injured workmen.

The choice of personal consumer expenditures as a frame of reference in this study should not be interpreted as an attempt to belittle the importance of physicians who serve in the local, state, and federal public health services. The decision to use this concept for medical care expenditures does, however, permit an appraisal of this quarter century unencumbered by a great many factors that would lead into a discussion of the inherent nature of government and its proper function in our society. This decision does not, and cannot, deny that during the quarter century covered the role of government has increased. But unless we could measure its increase—from 8% to 23.5%—in all areas of expenditures (for example, food), we would have no frame of reference for the treatment of these public expenditures for "medical care"; hence, this topic must be put aside as a separate project. Accordingly, we shall confine our attention to the private part of the economy.

Data on personal consumer expenditures will be presented for medical care, for all consumer expenditures, and for certain classifications of consumer expenditures other than medical care, in order to permit the reader to make comparisons among the various categories. The dollar amounts, and in some cases the percentages, represent slight variations from those previously published by this Bureau. This is because the Department of Commerce has constantly endeavored to improve the quality and scope of its estimates and because it has reworked many of the income and product series for the whole 25-year period in order to reflect additional data sources and improvements in estimating techniques. In some cases the revisions of the more detailed components have been rather substantial.

---

[1] Davis, M. M.: Medical Care for Tomorrow, New York, Harper & Brothers, 1955.

Personal Consumer Expenditures

Personal consumer expenditures are those dollars spent by individuals for the conduct of their personal lives. (The Department of Commerce now uses the term "personal consumption expenditures" in place of the former term "personal consumer expenditures"; the older term is used herein except in appendix table A.) As defined by the Department of Commerce these expenditures exclude taxes and capital goods. "Personal Consumption Expenditures consists of the market value of purchases of goods and services by individuals and nonprofit institutions and the value of food, clothing, housing, and financial services received by them as income in kind. It includes the rental value of owner-occupied houses but does not include purchases of dwellings, which are classified as capital goods" (page 59). Some comments on the Department of Commerce methods of estimating, and descriptions of the breakdowns and sources used in deriving the aggregate, Total Personal Consumer Expenditures, from which the data for tables 1 to 5 were derived, are presented in the appendix. Personal consumer expenditures amounted to 78,952 million dollars in 1929, they declined to 46,392 million dollars in 1933 (the low point of the depression), and they have increased by varying amounts each year since then. (See column (14) of table 1 and the shaded insert in chart I.) In 1953 total personal consumer expenditures amounted to 230,080 million dollars, 2.9 times the amount for 1929. Food, of course, was the largest item, increasing from 19,535 million dollars in 1929 to 71,844 million in 1953, from 24.7% of total personal consumer expenditures to 31.2% in 1953. The amount spent for medical care rose from 2,937 million to 10,001 million dollars.

1953........	577	5.77	562	5.62	887	8.87

For brief descriptions of these three items see footnote to table 1, column (7).

An examination of table 1 and chart I will clearly indicate that the total dollar amounts spent for all consumer items, for medical care and each of its five components, and for the selected consumer items declined during the early 1930's and rose rapidly during the 1940's. Of the 1953 total, of the 10,001 million dollars for medical care, 2,815 million was for physicians' services, followed by 2,602 million for hospital services, 1,615 million for drugs and sundries, 943 million for dentists' services, and 2,026 million for all other medical care. The amount spent for physicians' services, although somewhat greater than the amount spent for hospital services, involves the treatment of several dozen times as many patients as were admitted to nongovernmental hospitals, for each one of whom the nonprofit hospital paid out an average of about $177. The need for a frame of reference other than total dollars is obvious. In addition to total personal consumer expenditures, this table and this chart present the amount spent for alcoholic beverages, tobacco, personal care, and jewelry. These items were selected because the amounts spent for them were comparable to the amount spent for medical care or one of the five components; furthermore, some of these items, like medical care, are purchased irregularly. There is no intention to imply that any one consumer expenditure item has an exact counterpart in the entire series of several hundred items. The presentation of the data for these selected items should enable many readers to gauge the relative size of medical care expenditures, even though the national aggregate of total personal consumer expenditures seems vast and therefore rather hazy. No moral judgment is

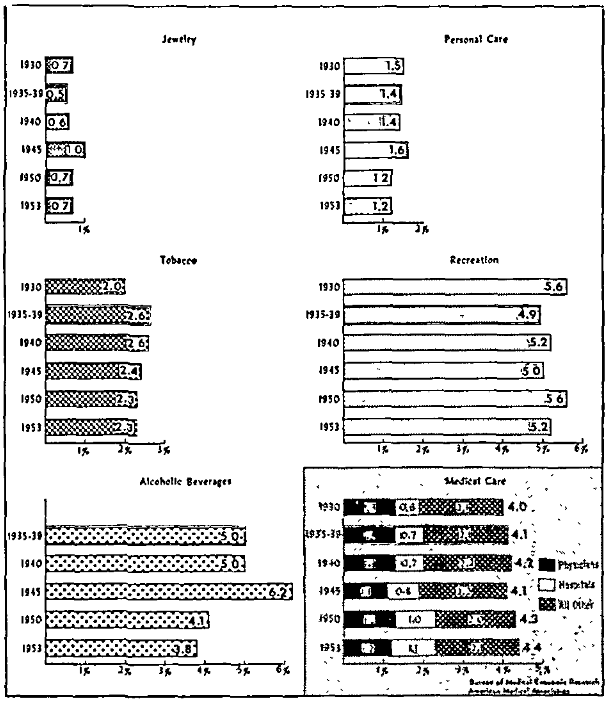

Chart II.—Selected personal consumer expenditures as percentages of total consumer expenditures, 1930-1953. Source: U. S. Department of Commerce.

implied in the choice of these selected items, for they are merely a record of how the people of the United States, enjoying the benefits of a free society, chose to spend their money.

Another group of items was selected—owner-occupied nonfarm dwellings; shoes; furniture; fuel (except gas) and ice; electricity, gas, and water; and user-operated transportation. Data for this second group of six selected items are presented in tables 1A (dollars), 2A (percentage of total personal consumer expenditures), and 4A (percentage of 1935-1939 average); no comments will be made on these data. Although this alternate set of selected items does not meet the test of similarity of amount as well as the first, some readers may prefer the second set; they should help to provide additional comparative perspectives for the medical care items. The dollar expenditures for the medical care items and the first group of selected items are shown as percentages of total consumer expenditures in table 2 and, for selected years, in chart II. Except for 1929 and 1930 the total spent for medical care was slightly above 4.0% of total personal consumer expenditures; for 1930, 3.99% and for 1929, only 3.72%. A careful search was made to try to determine the reasons for the unusually low percentage for 1929, but no satisfactory explanation could be found. We doubt that the lack of reported personal consumer expenditures for alcoholic beverages in 1929 was responsible for this abnormally low percentage for medical care expenditures, or for other percentages. Some students of national aggregates have suggested that the 1929 data should not be criticized too much because it was the first year in the Department of Commerce series. Nor can the low percentage be attributed entirely to the prosperity of 1929, because the percentages in later prosperous years have been above 4.0. Perhaps the most plausible explanation is the relatively small amount spent for hospital services in that boom year.

In general, it can be stated that the percentage spent for tobacco has been slightly less than twice that spent on physicians' services, which, in turn, has been slightly less than the percentage spent for personal care but somewhat greater than the percentage spent for jewelry. The percentage spent on recreation has been consistently greater than the percentage spent for all forms of medical care, which, in turn, was less than the percentage spent on alcoholic beverages from 1935 to 1949, and higher since.

Brief descriptions of the items (not the type of expenditure), arranged by column numbers, are presented below.

(2) Owner-Occupied Nonfarm Dwellings: Space-rental value, covering heating and plumbing facilities, water heaters, lighting fixtures, kitchen cabinets, linoleum, storm windows and doors, window screens, screen doors, and window blinds or shades. It excludes other furnishings, equipment and related services—furniture, stoves and ranges, refrigerators, repairs of furniture and appliances, fuel, electricity, etc.

(3) Shoes: Includes shoes and other footwear, shoe cleaning and repair.

(4) Furniture: Includes furniture; and semidurable house furnishings, consisting mainly of textile house furnishings (except those specified elsewhere), including piece goods allocated to house furnishings use, and lamp shades, brooms and brushes.

(5) Other Fuel and Ice: All fuel and ice except those included in column (6).

(6) Electricity, Gas, and Water: A division of Household Utilities on basis of classification as service utilities.

(7) User-Operated Transportation: Includes new cars and net purchases of used cars, tires, tubes, accessories, and parts; automobile repair, greasing, washing, parking, storage and rental, gasoline and oil: bridge, tunnel, ferry and road tolls; and automobile insurance premiums less claims paid.

BOOM IN OBSTETRICS AND PEDIATRICS

Perhaps the largest factor in the increase in dollars (from 5,042 million to 10,001 million) and in the percentage (from 4.14 to 4.35) spent for medical care since the end of World War II in 1945 is the increase in the number of births. They rose from 2,700,000 in 1945 to 3,900,000 in 1953, and the birth rate rose from 19.5 to 24.7. The proportion of all births in (registered) hospitals also increased, from 72% to 85%. Ideally, medical care expenditures should be divided into those for disease, for accidents, and for childbearing; such a division would show surprisingly large amounts for accidents and childbearing. It is the increase in the latter—an increase of 1,200,000 "bundles of joy"—that has been primarily responsible for increasing the percentage spent for medical care from 4.14 in 1945 to 4.35 in 1953. In pointing out the role of childbearing in this eight-year rise in the percentage spent for medical care, our purpose is not to quarrel with the classifications of the Department of Commerce but to warn against the misuse of the over-all data on medical care expenditures. The medical costs of childbearing are properly considered in the category of medical costs, but interpreting this increase in the percentage of consumer expenditures made for medical care since the end of World War II as a proof of high medical care prices or as an indication that our nation is becoming less healthy would be entirely unfounded.

It would be difficult to choose a completely satisfactory set of assumptions for the purpose of measuring the precise amount of this postwar increase attributable to the increase in the number of births or to the birth rate after allowing for some gain in population for reasons other than births. It would also be necessary to employ assumptions suitable to the early part of this quarter century when the birth rate and the number of births were decreasing. We have made certain assumptions that allow for a smaller increase in births and, consequently, a smaller increase in obstetric fees, in preparing some exploratory computations. They indicate that the percentage spent for medical care in 1953 would have been reduced from 4.35 to 4.2, possibly to 4.1. The computations are too preliminary to warrant presentation herein. Certainly, the increase in births has probably been the greatest single factor in the moderate but steady rise in the percentage spent for medical care during the last eight or ten years of this quarter century. Moreover, physicians have contributed to the high birth rate; reduction of the maternal mortality rate to a very low level has practically eliminated the mortal fear of childbearing.

The enormous baby boom since World War II has had a secondary effect on personal consumer expenditures for medical care. A number of studies have been made on the age and sex incidence of the demand for the services of physicians and hospitals. A compilation of these studies has been made by Collins and co-workers.[2] On the whole, these studies show that the frequency of use of health services was higher for the preschool age group than for other age groups. Hence the great increase in the number of young children since World War II has probably produced a disproportionate increase in the per capita demand for the services of physicians and hospitals. During their adult years the survivors of this large group of children will greatly expand the potential labor force and should tend to increase all the national economic aggregates. But the time elapsed since the baby boom started after World War II has been insufficient for them to increase national income. So the secondary effect of the great increase in births—in the field of pediatrics rather than obstetrics—may actually be greater than the primary effect of the costs of childbearing. Furthermore, although pregnancy is not a disease, accidents, disease, and the prevention of disease account for the medical and hospital services for small children. Apparently, the number of annual births will exceed 4 million for several years to come, and the number of preschool children shows no signs of diminishing.

DISEASE, ACCIDENTS, AND BABIES

Unfortunately for our present purposes, the methods used by the Department of Commerce in preparing the annual estimates of personal consumer expenditures for the services of physicians and hospitals do not permit a separation of either the costs of childbearing or the costs of frequent medical care for young children. Without such breakdowns it is not possible to utilize a standardized age distribution in estimating the separate amounts of medical care costs resulting from these two factors. Pending the development of the necessary breakdowns, we conclude this portion of the analysis with the admonition that a very considerable portion of the increase in the dollars spent by consumers for medical care, especially for the services of physicians and hospitals, during the post-World War II years should be attributed to childbearing and the great increase in both the number and proportion of young children in our population. This admonition should be interpreted as a recognition that medical care expenditures have risen, both absolutely and relatively; but the rise does not indicate a deterioration in the health of the American people or, as will be shown in more detail later, rapidly rising prices in all fields and aspects of medical care.

The full implication of personal consumer expenditures for medical care could be presented with clarity and significance if these expenditures could be divided into three parts: those for diseases, those for accidents, and those for childbearing. Furthermore, adjustments for changes in the age distribution of the population in any of these three types of expenditures would increase the significance of the data. Increases and decreases in each of these three items would clarify the role of medical care expenditures in the whole gamut of personal consumer expenditures. At the present time this threefold division cannot be made.

PEAKS AND TRENDS

Prior to 1945, in this quarter century two peaks in personal consumer expenditures for medical care should be noted. The highpoint of 4.28% in 1944 undoubtedly reflects the rationing of many commodities and services, the scarcity of certain drugs, and the induction of about two-fifths of the physicians into military service—an abnormal year from any standpoint. The first peak of 4.31% in 1932 probably reflects the stability of some medical expenditures in the depth of a great depression. The percentage spent for physicians' services (column (4), table 2) has fluctuated from a low of 1.09 in 1943 to 1.34 in 1931 and 1932. On the other hand, the percentage spent for hospital services has shown a rather steady and sharp upward trend to a highpoint of 1.13 in 1953. Expenditures for the services of dentists have varied between 0.41% in 1952 and 1953 and 0.67% in 1931, with a noticeable downward trend during the quarter century. The percentage spent for drugs and sundries (outside of hospitals) has followed an erratic course, rising to a World War II peak and then declining; for all other medical care, the percentage rose rather steadily from 0.62 in 1929 to 0.88 in 1953.

Since the American people were free to spend more on medical care and less on some other item, for example, recreation, their reasons for not doing so are important. Even a cursory examination of the types of expenditures included under medical care by the Department of Commerce will indicate that some medical care expenditures are necessities and some are luxuries within the ordinary meaning of those terms. A private hospital room with all the extras is, for some patients, a common example of the latter. A reasonably satisfactory explanation of why the people did not choose to spend more for medical care and less for recreation would carry us too far into the realm of marginal utility and value. People tend to spend their money so that the marginal utility of each dollar spent is equal to the marginal utility enjoyed by any other dollar spent. At the outer fringe of medical care there are a great many types of expenditures that many would consider to be almost frivolous; in fact, many people would prefer a pleasure trip to such small additions to their well-being as can be made by the purchase of some of these relatively unimportant medical care items. In the end it is largely a matter of degree. The freedom of the people to distribute their personal consumer expenditures as they see fit tends to keep these marginal utilities equated.

THE MEDICAL CARE DOLLAR

The changes in the percentages spent for each of the five medical care items can be presented more clearly by changing the frame of reference from total personal consumer expenditures to those for medical care only. The total amount spent for medical care has been set equal to 100% in tables 3 and 3A, and in charts III, IIIA, and IV. We have called this smaller frame of reference the medical care dollar. The portion of the medical care dollar spent for physicians' services has declined from 32.65 cents in 1929 to 28.15 cents in 1953; this decline is evident in the top line on chart III and in the black portion of the medical care dollar in chart IV—from 33 cents in 1929 to 28 cents in 1953. It is presented in more concise statistical form in chart IIIA as a trend line with a definite downward slope during this quarter century; the straight line trends were removed from chart III for the sake of clarity. There was also a definite downward trend in the portion of the medical care dollar spent for the services of dentists, from 16.41 cents in 1929 to 9.43 cents in 1953. This downward trend is roughly indicated on chart III and definitely by the downward trend of the straight line on chart IIIA and the smaller wedge of the pie in chart IV—from 16 cents to 10 cents. The pie chart also gives a quick visual presentation of the decline in the portions of the medical care dollar spent for the services of physicians and dentists combined, from 49 cents in 1929 to 38 cents in 1953. This decline in the percentage of the medical care dollar that American consumers spent for the professional services of physicians and dentists is one of the outstanding changes in the economics of medical care in this quarter century. (The average relationship between the percentages of the medical care dollar for each of the five items may be described by fitting straight lines [$y=a+bx$] for the 25-year period to the values plotted on chart III by the method of least squares. The results are five derived "trend lines" shown on chart IIIA. The formulas used in plotting these trend lines were: physicians, $y=32.44-0.19x$; hospitals, $y=13.76+0.40x$; for others, $y=15.43+0.19x$; drugs, $y=22.35-0.15x$; and dentists, $p=16.03-0.24$.)

[2] Collins, S. D., and others: Sickness Experience in Selected Areas of the United States, Public Health Monograph no. 25, Public Health Service Publication no. 390, U. S. Department of Health, Education, and Welfare, 1955.

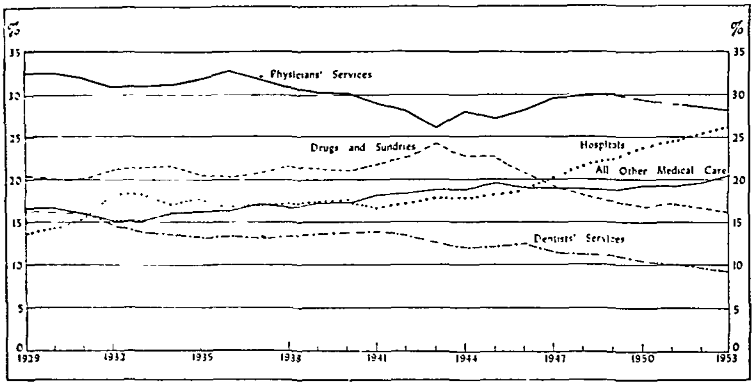

Chart III.—Percentage distribution of expenditures for medical care, 1929-1953. Source: U. S. Department of Commerce.

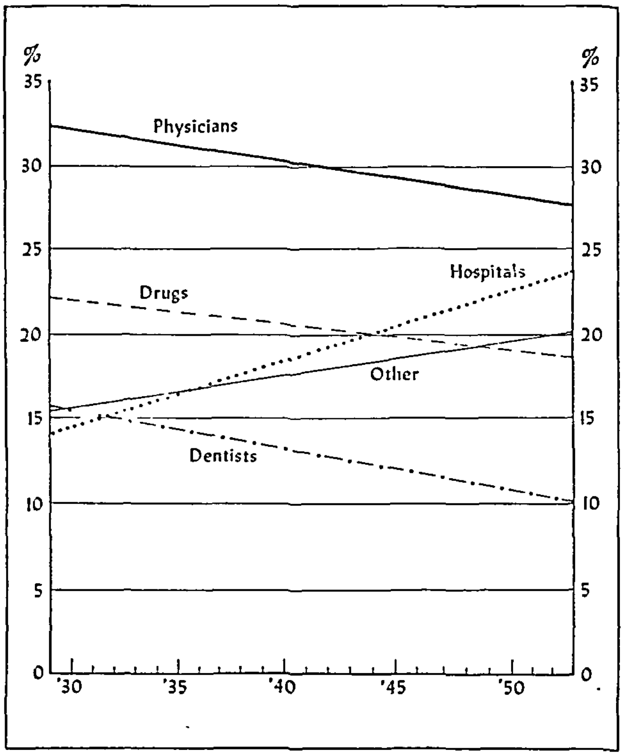

Chart IIIA.—Trends in portions of the medical care dollar. Source: U. S. Department of Commerce.

The portion of the medical care dollar spent for hospital services rose sharply from 13.72% in 1929 to 26.02% in 1953. This rise in the hospital portion of the medical care dollar can be seen by following the line for hospitals in chart III, but it is much clearer in the sharp upward slope of the straight line in chart IIIA and in the widening wedge of the pie of chart IV—from 14 to 17 to 26 cents. Although we have elsewhere raised some questions regarding the Department of Commerce estimates of total and the breakdowns of personal consumer expenditures for medical care, this obvious upward trend in expenditures for hospital services is not surprising. It was during this quarter century that the American people began to patronize their hospitals frequently, beginning of course with birth itself and continuing throughout life. The number of patient days in nongovernment hospitals rose from 77 million in 1929 to 123 million in 1953 (compiled from the annual hospital numbers of THE JOURNAL of the American Medical Association). Unquestionably the rapid expansion of hospital insurance has played an important role, but our point here is merely that the phenomenal health progress attained during this quarter century would probably have been impossible if the portion of the medical care dollar going to hospitals had not increased sharply. Change is inherent in a dynamic economy, and the increase in the economic importance of hospitals is another of the outstanding changes in the economics of medical care during the quarter century.

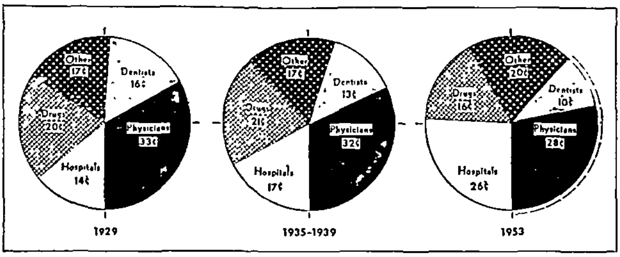

Chart IV.—The medical care dollar. Source: *Survey of Current Business*, 1954 National Income Supplement.

Chart IIIA seems to forecast a larger share of the medical care dollar for hospital services than for physicians' services. A simple extrapolation of these two trend lines indicates that they will intersect by 1960. (Preliminary data for 1954 suggest it may happen before 1960.) We do not make that as a positive forecast because trend lines are, of course, statistical measures of the past and not too reliable as a forecasting device. Nevertheless, there is a strong possibility that the American consumer will be spending more for the services of hospitals than for the services of physicians sometime in the 1960's. The portion spent for drugs and sundries (outside of hospitals) was 20.57% in 1929, 24.21% in 1943, and only 16.15% in 1953. This peak in 1943, shown in chart III, was probably a result of the wartime scarcity of some drugs; the development of antibiotics, which were originally very expensive; and possibly the tendency of hard-pressed civilian physicians to prescribe more drugs than usual during the war days when two-fifths of the physicians were in the armed services. Moreover, this category includes not only consumer expenditures for prescriptions but also the amounts spent by consumers for patent medicines and for such things as clinical thermometers, rubber sundries, arch supports, and some articles of personal hygiene; the amount spent for prescriptions alone is not available. We hesitate to make an extrapolation of the trend for this item because of the extremely rapid progress in the development of new drugs.

We have incorporated into all other medical care, which rose rather steadily from 16.65% in 1929 to 20.26% in 1953, the Department of Commerce's separate estimates for the three remaining items—ophthalmic products and orthopedic appliances, other professional services, and medical care and hospitalization insurance (premiums less claims). These are shown separately in table 3A. The portion spent for ophthalmic products and orthopedic appliances rose from 4.46% in 1929 to 7.33% in 1943 and decreased to 5.77% in 1953. The portion spent for other professional services—which the Department of Commerce previously divided into six categories: osteopathic physicians, chiropractors, chiropodists, pediatrists, private-duty trained nurses, practical nurses and midwives, and miscellaneous curative and healing professions—declined rather steadily from 8.51% to 5.62%; the decision of the Department of Commerce to give only one amount for these six items precludes any comment on any one of them.

medical care—489 million dollars in 1929 to 2,026 million dollars in 1953 [column (7), table 1]. The increase in this overhead item also accounted for one-ninth of the 7,064 million dollar increase in total personal consumer expenditures for medical care between 1929 and 1953; this increase was also 42% of the increase between 1929 and 1953 in the amount spent for physicians' services, 34% of the increase for hospitals, 77% of the increase for drugs and sundries, and 169% of the increase for dentists' services. It is not, however, a medical care item per se. The rise has been quite steady throughout the quarter century. (Preliminary data for 1954 indicate another jump in this overhead item.)

The inclusion of this item in medical care expenditures—with which we have no quarrel—means that the overhead cost of operating voluntary health insurance plans is allocated by the Department of Commerce to medical care expenditures as would be an obstetrician's fee, a week's stay in a nongovernment hospital, or the price of a bottle of penicillin purchased outside of the hospital. Obviously the function of insurance is to spread risks, not losses. If all people were to be covered by all the necessary forms of health insurance, the overhead cost of operating these insurance companies and plans would be an added cost of medical care over and above the indemnities paid. This cardinal point should be stressed over and over again. Sometimes it seems that, when a labor union is trying to induce an employer to pay an extra few cents an hour for health insurance, the purchase of aspirin tablets is made to appear as a dire hardship for the worker. Payment of these small claims increases the overhead cost of operating an insurance plan; it increases the total cost of medical care to the American people. Provisions for the payment of these "five and dime claims" under insurance arrangements add to the total cost of medical care to the American people and, thereby, raise serious doubts about the wisdom of such provisions. The fact that such employer costs are passed on to the ultimate consumer decreases the interest of some people in such matters but cannot decrease the extra dead weight added to the expenditures of the American people for insurance overhead for medical care. Most of the increase from 108 million to 887 million dollars probably resulted from the rapid expansion of voluntary health insurance in the United States rather than from the cost of handling so many small claims. Coverage of almost 100 mi [illegible] some form of hospitalization insurance in 1953 [illegible] a considerable overhead charge. The una [illegible] data on the cost of handling these small cl [illegible]

Source: Table 1

INSURANCE OVERHEAD

Special attention must be given to the last two columns in table 3A, medical care and hospitalization insurance. In former years this item was divided into: (1) net payments to group hospitalization and health associations, (2) student fees for medical care, (3) net payments of accident and health insurance, and (4) net payments of mutual accident and sickness benefit associations. The former terms and the present single term, medical care and hospitalization insurance, are somewhat misleading to many students of insurance. The amounts are really premiums less claims except for student fees for medical care and medical expenses of group health associations; the term overhead or operating expense of the insurance carrier would be more descriptive, even though some of these dollars (on a cash basis) went into reserves. The actual benefits to policyholders are, and should be, excluded, for they enter the picture of medical care expenditures through other doors. The amount of this insurance overhead item increased from 108 million dollars in 1929 to 887 million in 1953, or from 3.68% of medical care expenditures to 8.87%; in 1945 the amount was only 374 million dollars. Thus, the increase in medical care and hospitalization insurance overhead accounted for 779 million dollars of the 1,537 million dollar increase in the item all other failure of the voluntary insurance plans and companies to make such data available. Whatever the division may be, our point here is merely that the overhead cost of operating voluntary health insurance plans is a part, and a rapidly increasing part, of the amount classified as personal consumer expenditures for medical care. But this is not an argument for governmental compulsion, in the hope that, despite the greater overhead, it could be spread more thinly over all taxpayers. This insurance overhead item of 887 million dollars could, at least theoretically, have been distributed among the four major categories of medical care. The major portion would, of course, have been assigned to hospitals, because of the extremely large volume of hospital insurance, and little or none to dentists' services. It is to be hoped that the Department of Commerce will soon be able to develop the necessary breakdowns of this insurance overhead item in order that the allocations can be shown regularly. The importance of this suggestion for future years rests on the assumption that this item will continue to show the most rapid growth of the four major and three minor items; in 1953 this amount for insurance overhead was 94% of the amount spent for dentists' services, 55% of the amount spent for drugs and sundries, 34% of the amount spent for hospital service, and 32% of the amount spent for physicians' services.

The changes in the amounts spent by consumers for the five medical care items and the five selected consumer items shown in tables 1 and 2 are also revealed in the index numbers presented in table 4. The base period used is 1935-1939, and the *average amount for these five years for each item is set equal* to 100. This method of presentation avoids the use of dollars; the magnitude of the index for any year is relative to the five-year base period average. The index number for the year for total personal consumer expenditures [column (14)] provides a standard of comparison for the index number for any one of the items; the decline from 124 in 1929 to 73 in 1933, past the 200 mark in 1946 (230) and the 300 mark in 1950 (305). For 1953 the index number was 361; that is, total personal consumer *expenditures in 1953 were 261% above the 1935-1939 level.* On the other hand, the 1953 index for total medical care was 385, for physicians' services 343, for hospitals 581, for drugs and sundries 296, for dentists' services 273, and for all other medical care 463. For the first set of five selected items for 1953 the indexes were: 279 for alcoholic beverages, 378 for recreation, 328 for tobacco, 288 for personal care, and 517 for jewelry. An interesting coincidence is that the index number for these 10 items combined—5 medical care and 5 selected—was 342 for 1953 and for physicians' services 343.

The Department of Commerce presents 67 numbered items and 23 subitems in its table 30, Personal Consumption Expenditures, by Type of Product, 1929-1953 (pp. 206-209). These are grouped into 12 classes shown in our table 5. (As noted, table 5 is omitted here but will appear in the reprints.) The items included in each class are defined in extensive footnotes. They are presented in table 5 in millions of dollars (part A), as index numbers based on 1935-1939 (part B), and as percentages of *total personal consumer expenditures (part C). The largest class* of expenditures is food and tobacco. [The amounts for tobacco are shown separately in columns (10) and (11) of our tables 1 and 2.] Although dwarfed by food and tobacco, the other large items were: household operation; housing; clothing, accessories, and jewelry; and transportation. The data in column (7) of table 5, medical care and death expenses, exceed the amounts shown in other tables for medical care alone by the amounts for death expenses, which rose from 607 million dollars in 1929 to 1,168 million in 1953. Our exclusion of death expenses from this broad category should not imply any criticism of the Department of Commerce in combining death expenses and medical care as one of the 12 broad groups of personal consumer expenditures; death expenses seem to fit better there than in any of the other 11 major categories. Table 5 provides, therefore, a broad perspective of how American consumers chose to spend their money in each of these 25 years. Economically, they were free to spend their money in a different fashion. This table, then, is the record of the collective choices of the American people during the quarter century.

(Concluded next week)

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Army and Navy: Induction Under "Doctor-Draft" Law.—The petitioner, a licensed physician, filed suit for a writ of habeas corpus to obtain a discharge from the U. S. Army. After a denial of the writ by the trial court and the court of appeals, the petitioner was granted certiorari to the United States Supreme Court.

The petitioner was over the age limit set for general induction, but he was subject to conscription under a special provision of the draft law providing for induction of men of certain medical and allied specialist categories. He had received his professional training during World War II at government expense, but he had spent less than 90 days in active service. He was, therefore, one of the first to be called for service under the medical specialist provision of the draft law. After his induction the petitioner was refused an officer's commission, because he refused to answer certain loyalty questions (referring to membership in the Communist Party or Communist-front organizations), claiming his federal constitutional privilege. He was, however, assigned duties as a medical laboratory technician. Three issues were presented: 1. Must the Army grant the petitioner a commission? 2. Must the Army assign only those duties to the petitioner that are consistent with his position as a medical specialist? 3. May the petitioner obtain a military discharge if the Army refuses to assign him to such duties?

The Supreme Court held that it was the function of the President of the United States to commission officers in the Army, but that under the law the President was not required to grant the petitioner a commission, even though doctors inducted under this special provision are customarily given commissions. The Court's holding was based on a 1950 act, wherein Congress provided that the Army Medical Corps shall consist of officers "and such other members of the Army as may be assigned thereto by the Secretary of the Army. . . ." The Court also held that the petitioner, having been specially inducted as a doctor, was entitled to be assigned duties falling within "medical and allied specialist categories." To hold otherwise, said the Court, would be to permit an unlawful discrimination. Finally the Court found that the petitioner had been assigned medical duties. The petitioner claimed that even though he was assigned such duties, he was not permitted to do all the things that a man of his experience was entitled to do. The Court said that the courts should not entertain suits to determine whether or not a particular serviceman was being assigned tasks suited to his particular capabilities, since such decisions were solely within the discretion of the military officials.

Accordingly, the Supreme Court affirmed the judgment for the Army and denied the petitioner a discharge. *Orloff v. Willoughby, 73 S. Ct. 534 (U. S., 1953).*

Drunkenness: Privilege Against Self-Incrimination; Consent.—The defendant was tried and convicted of the offense of driving while intoxicated. From such conviction the defendant appealed to the court of criminal appeals of Texas.

After an automobile accident in which the defendant was involved, the defendant was taken to a hospital for treatment. While there a laboratory technician told the defendant that he intended to take a specimen of the defendant's blood. The defendant offered his arm in the proper position, and the sample was taken without any objection by the defendant. At the trial a toxicologist testified that the blood sample contained 2.2 mg. of alcohol per cubic centimeter of blood and that such percentage (0.22%) was indicative of intoxication. The defendant objected to this testimony on the ground that it violated his constitutional prohibition against self-incrimination.

The court held that where a blood specimen is taken with the consent of the defendant no constitutional prohibition against self-incrimination is violated by the subsequent use of the specimen in evidence against the accused. Accordingly, the conviction of the defendant was affirmed. *Marshall v. State, 262 S. W. (2d) 491 (Texas, 1953).*

MEDICAL NEWS

CALIFORNIA

County Society Honors Dr. Murray.—The Napa County Medical Society recently paid tribute to Dr. Dwight H. Murray, President-Elect of the American Medical Association, at a testimonial dinner attended by more than 100 physicians from Napa County and elsewhere. The August issue of the society's bulletin carries a picture of Dr. Murray on the cover, an editorial tribute, and two pages of photographs taken at the dinner.

Council on Sports Medicine.—An organizational meeting of a group tentatively named the Western Council of Sports Medicine was scheduled for Aug. 22 in the Los Angeles County Medical Association Auditorium, with Dr. Wilmer B. Buckland of Van Nuys and Dr. William D. Lindgren, medical director of the Sister Kenny Polio Hospital, El Monte, as co-chairmen. The new organization of physicians and others will undertake research and analysis of sports programs and of the treatment of athletic injuries, training methods, and standards of physical fitness, and a study of physical education programs in general. Membership will be open to members of the Los Angeles County Medical Association and to certain qualified laymen whose profession or hobby brings them into close association with athletics.

CONNECTICUT

Society News.—Newly elected officers of the Connecticut Public Health Association include Dr. William Hart Upson, Suffield, president; Dr. Edward M. Cohart, New Haven, president-elect; Leonard F. Menczer, D.D.S., Hartford, vice-president; Mrs. Claire Heinhardt, West Hartford, secretary; and Mrs. Eloise K. Erkler, treasurer (reelected).

Annual Clinical Congress.—The 30th Clinical Congress, sponsored by the Connecticut State Medical Society and Yale University School of Medicine, will convene at the Yale-New Haven Medical Center, New Haven, Sept. 14-15. The following program will be presented Wednesday at 10 a. m. in the Brady Auditorium:

Clinical Aspects of Disorders of Coagulation, Mario Stefanini, Brighton, Mass.
Anticoagulants, William T. Foley, New York, and Henry I. Russek, Staten Island, N. Y.
Hypophysectomy for Breast Cancer, Bronson S. Ray, New York.
Chemotherapy of Neoplastic Disease: Its Relationship to Surgery, Joseph H. Burchenal, New York.
Changing Concepts of Cancer Surgery, J. Englebert Dunphy, Boston.

*Simultaneously, in the Fitkin Amphitheater, Dr. David Hur*witz, Cambridge, Mass., will discuss "Use of Various Types of Insulin," after which Dr. Max Miller, Cleveland, will consider "Use of Fructose in Treatment of Diabetic Acidosis." Luncheon, 12:30 p. m., will be preceded by a clinicopathological conference conducted by Dr. Benjamin Castleman, Boston, and followed by panels on low back pain and on headache. The Thursday session in the Brady Auditorium will be devoted to panels on infectious hepatitis, immunization against poliomyelitis, drug therapy in hypertension, and new tranquilizing drugs. The following program will be presented in the Fitkin Amphitheater:

Intractable Heart Failure: Its Management, E. Hugh Luckey, New York.
Management of Patients with Arterial Disease, Fiorindo A. Simeone, Cleveland.
Clinicopathological Conference, H. Edward MacMahon, Boston.
Indications for Emergency Surgery in Biliary Tract Disease, Henry Doubilet, New York.

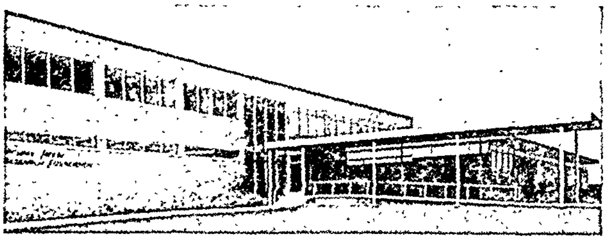
Registration, admitting one to all sessions, will be $3. Medical students, interns, and residents will be guests of the congress, if properly certified. Address inquiries to the Connecticut State Medical Society, 160 St. Ronan St., New Haven 11.

ILLINOIS

New State Birth Record.—According to the state department of public health more babies were born in Illinois in 1954 than in any previous year of record. Last year's estimated total of 217,000 live births exceeds by about 10,000 the previous high established in 1953. The increase in births in 1954 and the low death rate combined to give the state a natural increase in population of close to 125,000. Deaths among babies under one year of age totaled an estimated 5,400 in 1954, or 25 per 1,000 live births. These figures compare with a total of 5,326 infant deaths in 1953 and a rate of 25.8. Neonatal mortality, however, among babies under 28 days of age continued at about the same rate as in 1953—about 18 deaths per 1,000 live births. Despite the record number of births, maternal mortality continued to decline in Illinois in 1954.

Chicago

Michael Reese Research Foundation.—An open house will mark the official opening of the new $1,250,000 building of the Michael Reese Foundation Sept. 11, 1-4 p. m. The building, which will be dedicated in honor of the late Dr. Sidney O. Levinson, first executive director of the foundation, is a two-story, reinforced concrete structure, occupying the southern half of the block between Ellis and Lake Park avenues, north of 31st Street. The northern half will be used as a park adjacent to the Friend Convalescent Home, to be constructed by Michael Reese Hospital in 1956. The first floor of the building contains facilities for blood donors, a blood bank, and laboratories for preparation of plasma and serums required for community service. The second floor is devoted to research laboratories and offices. Dr. Albert M. Wolf is executive director of the foundation.



Michael Reese Research Foundation

IOWA

General Practice Meeting.—The annual meeting of the Iowa Academy of General Practice will be held at the Hotel Savery, Des Moines, Sept. 15-16. Presentations by out-of-state speakers will include "Recognition of Neurotic and Psychotic Patients in Medical Practice" and "The Suicide" by Dr. Louis G. Moench, Salt Lake City, and "Emotional Tragedies in Infancy and Childhood" and "Teen-Age Problems" by Dr. John G. Young, Dallas, Texas.

KANSAS

Fluorination of Water Supply.—Coldwater, the 24th Kansas city to fluorinate its public water supply, is the first city in the state to cooperate with a private utility company to give the citizens fluorination. The city purchased equipment and supplies, and the Western Light and Telephone Company, which owns the water system, handles operation, maintenance, and testing.

Society News.—The Kansas Radiological Society recently elected Dr. Abraham M. Cherner, Hays, president; Dr. Kenneth Allen, Kansas City, vice-president; and Dr. George S. Ripley Jr., Salina, secretary-treasurer.——At a meeting of the Kansas State Pediatric Society in Emporia, Sept. 10, Dr. James M. Baty, Boston, will present "Psychosomatic Problems," "Emergencies

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

in the Newborn," and "Colic." Dr. Herbert A. Wenner of the University of Kansas Medical Center, Kansas City, will discuss "Current Research in Poliomyelitis." Physicians who are members of the Kansas Medical Society are eligible to attend.

KENTUCKY

Needs of Handicapped.—The governor has appropriated $10,000 from his emergency fund for a survey by the state's Legislative Research Commission to determine the needs of the handicapped in Kentucky. In addition to Dr. J. Gant Gaither, Hopkinsville, president-elect of the Kentucky State Medical Association, other physicians on the committee are J. Murray Kinsman and Asa Barnes, Louisville, and Marshal M. Jones and Franklin B. Moosnick, Lexington.

Auxiliary Mental Health Activities.—The mental health committee of the woman's auxiliary to the Jefferson County Medical Society, set up in January, 1954, to investigate local needs and possible avenues of volunteer service in an effort to correct and check the increase of mental illness, reports a successful project in improving the morale and pleasant living of 180 attendants working with patients at the Kentucky General State Hospital at Lakeland. Through the efforts of the auxiliary, numerous social events were planned, which resulted in "boosting the morale of attendants . . . and hence contributing toward the service to mentally ill patients."

LOUISIANA

Faculty Promotions.—The following promotions of physician faculty members have been announced by the Tulane University of Louisiana School of Medicine, New Orleans.

Professors: Jack K. Wickstrom (orthopedics) and Donovan C. Browne (clinical medicine).

Associate Professors: James W. Burks Jr. and Lee D. McLean (clinical medicine); Jason H. Collins and John C. Weed (clinical obstetrics and gynecology); and Homer D. Kirgis (anatomy and clinical surgery).

Assistant Professors: Daniel W. Beacham and Frank G. Nix (clinical obstetrics and gynecology); Robert Birchall, Edward R. Christian, Stanley Cohen, Allan M. Goldman, Richard H. Linn, Arthur R. Payzant, Thomas E. Weiss, and Norton W. Voorhies (clinical medicine); Murl E. Faulk Jr. (neurology and surgery); Patrick H. Hanley and Charles R. Walters (clinical surgery); William D. Love (medicine); and Samuel M. Peacock Jr. (neurology).

MASSACHUSETTS

Institute of Psychiatric Treatment.—An Institute of Psychiatric Treatment will be held in the reception building of the Boston State Hospital Sept. 29 to Oct. 1. Dr. Leo Alexander and Dr. Robert Arnot will open the institute at 9 a. m. Thursday with "Combined Psychologic-Physiologic Treatment of Mental Disorder—Neurophysiologic Foundation," which will be followed by clinical demonstrations by Dr. Leo Alexander and Dr. Irving E. Gilbert, Boston. Group discussion at lunch will be concerned with "Experiences in Treating Schizophrenia." The afternoon session will be devoted to a symposium and group discussion on new drugs, including Thorazine and Serpasil. The Friday program will include a clinical demonstration on electronarcosis by Dr. Esther Bogen Tietz, Los Angeles; a group luncheon discussion of experiences in treating anxiety; a symposium on patient management and rehabilitation; and dinner, 7 p. m., at the Harvard Club. The Saturday session will include a clinical demonstration on electric coma by Dr. Brian C. Campden-Main, Petersburg, Va., and a symposium and group discussion on psychotherapy, in which that subject will be discussed by Dr. Hans Lowenbach, Durham, N. C., and "Analytic Psychotherapy of the Psychoses" by Dr. John N. Rosen, New York. Registration fee is $35. Correspondence may be addressed to Dr. Alexander, 433 Marlborough St., Boston.

MICHIGAN

Hospital News.—The Bon Secours Hospital presented its eighth annual clinic day program June 7 at Grosse Pointe. Dr. Dwight J. Dutcher, Grosse Pointe Farms, moderated the morning session and Dr. Joseph B. Woolfenden, Detroit, the afternoon session. For the evening program, Dr. Donald N. Sweeny Jr., Detroit, general chairman of the program, served as moderator.

State Society Wins Award.—For its program in recruiting and training medical associates to extend the best medical care to the greatest number of Michigan citizens, the Michigan State Medical Society has received the Grand Award for State Associations in the annual contest for outstanding activities sponsored by the American Trade Association Executives. A bronze plaque was presented at the 35th anniversary meeting of the association in Mackinac Island to Dr. William Bromme, Detroit, chairman of the council of the Michigan society. The society inaugurated the medical associates' recruitment and training program shortly after World War II, when it became apparent that there was great need for laboratory technicians, medical secretaries, nurses, and other specialists. Since that time, thousands of Michigan young people have been attracted to enter careers in many fields of medicine and health as a result of the MSMS campaign, educational facilities have been set up at a number of Michigan universities and junior colleges, and doctors have been encouraged to make greater use of medical associates in the interest of serving the maximum number of people.

MISSOURI

Dr. Moore Resigns as Dean.—Washington University, St. Louis, announces that Dr. Carl V. Moore, St. Louis, dean of Washington University School of Medicine for the past two years, has resigned and has been appointed Busch Professor of Medicine and head of the department of internal medicine. Dr. Moore, who succeeds Dr. W. Barry Wood Jr. in both posts, also will become physician-in-chief to Barnes Hospital. His appointments were effective Sept. 1, but he will continue as dean until a successor is named.

NEW YORK

Emergency Medical Institutes.—The state Office of Medical Defense has announced that its 1955 fall series of training institutes will inaugurate a program to train personnel to work in civil defense-improvised hospitals after an enemy attack. A short evening meeting providing an orientation to the use of the state mobile hospital outfit as the equipment unit of an improvised emergency hospital, set up in schools or other preselected buildings, will be open to physicians and hospital personnel. The mobile hospital outfit, which is being stock-piled throughout the state, will be used to equip 200-bed improvised emergency hospitals. The outfit contains sufficient equipment and supplies to keep the hospital in operation 10 days. Institutes will be held in 14 locations and will run from Sept. 15 through Nov. 15. All interested physicians are invited to attend one or all of the sessions. The following schedule has been announced for western New York:

Oct. 19, Buffalo, University of Buffalo, Capen Hall, 3435 Main St.
Oct. 25, Rochester, Rochester Academy of Medicine, 1441 East Ave.
Oct. 27, Corning, Corning Glass Center.
Nov. 2, Niagara Falls, Niagara Falls City Hall, Main Street.
Nov. 4, Jamestown, New York State Armory, Porter Avenue.

New York City

University News.—A psychology major emphasizing clinical psychopathology will be offered this fall by Barnard College and the Payne-Whitney Psychiatric Clinic of the New York Hospital-Cornell Medical Center. The course is designed to improve the students' understanding of work in psychiatric hospitals through clinical course work and experience on the floors at the Payne-Whitney Clinic. The program has been developed by Dr. Oskar Diethelm, psychiatrist-in-chief of the New York Hospital, and Richard P. Youtz, Ph.D., executive officer of the Barnard psychology department.

Dr. Philips in New Post.—Frederick S. Philips, Ph.D., head of the department of pharmacology, division of experimental chemotherapy, Sloan-Kettering Institute for Cancer Research, will become research consultant for the American Cancer Society on Sept. 6. In his new post, Dr. Philips will be concerned with research directed toward finding chemotherapeutic agents effective against cancer in man. Before joining the Sloan-Kettering Institute in 1946, Dr. Philips was associated with the University of Rochester (N. Y.); Yale University, New Haven, Conn.; Massachusetts Institute of Technology, Cambridge; and the

Medical Research Laboratory at Edgewood Arsenal, Md. While on the staff at Sloan-Kettering Institute, he served as assistant professor in the department of pharmacology, Cornell University Medical College.

OHIO

General Practitioners Meet in Dayton.—The fifth Annual Scientific Assembly of the Ohio Academy of General Practice will be held at the Dayton-Biltmore Hotel Sept. 20-21. Presentations by out-of-state speakers will include:

Management of Poliomyelitis, George J. Boines, Wilmington, Del.
Treatment of Acne, Alice E. Palmer, Detroit.
The Diarrheal Syndrome, Jerome Weiss, New York.
Use and Abuse of Hormones, John J. Bailey, Chicago.

OKLAHOMA

Chicago Position Accepted by John Hart.—John K. Hart, formerly associate executive secretary of the Oklahoma State Medical Association, has accepted a position in Chicago as executive secretary of the American Academy of Orthopaedic Surgeons. Mr. Hart had been with the state association for seven years. Mr. Don Blair has been appointed to succeed Mr. Hart.

Personal.—Dr. Kenneth W. Navin, Shawnee, city-county health director, was recently named "Knight of the Year" by the Shawnee Knights of Columbus.——Dr. Orange W. Starr, a past-president of the Creek County Medical Society, was honored at a picnic June 19 in Whitlock Park, in celebration of the 40th anniversary of his practice in Drumright. All "Starr brand" babies and their parents were invited as guests. A "This Is Your Life" sketch was presented, with state representative Lou S. Allard acting as master of ceremonies. A "stomp" dance was given by Indians from the Sac and Fox agency.——Dr. William E. Seba, Leedey, was recently given the honor of being the first to cross the new million dollar Camargo bridge. Dr. Seba is said to have crossed the South Canadian river near the bridge site more times than any other resident of the area, using practically every method of transportation, including fording the stream with horse and buggy.——Drs. J. R. Hinshaw, Oklahoma City, and Felix M. Adams, Vinita, were recently inducted into the Oklahoma Hall of Fame at a dinner in Oklahoma City. Dr. Hinshaw, who served with the Army at the headquarters of the Persian Gulf command during World War II, has been a staff physician at the University of Oklahoma Health Service since 1947. Dr. Adams has been medical superintendent at Eastern State Hospital, Vinita, since it opened in 1913.

PENNSYLVANIA

Pathologists Meet in Pittsburgh.—The middle eastern region of the College of American Pathologists, the Pennsylvania Association of Clinical Pathologists, and the Clinical Pathological Society of Pittsburgh will hold a joint meeting at the Roosevelt Hotel, Pittsburgh, Sept. 16-17. The Friday morning session will be devoted to a panel discussion on perinatal pathology and the afternoon program to a slide seminar, "Hazards of Therapy." Dr. A. Reynolds Crane, Philadelphia, will serve as moderator and Dr. Frank J. Dixon, Pittsburgh, as referee. (Slide sets will be sent to registrants two weeks before the meeting. Apply to Dr. Frank E. Sherman, Children's Hospital, Pittsburgh 13. Registration fee for slide seminar, $6.) The Clinical Pathological Society of Pittsburgh will be host at the social hour, 6 p. m., preceding the banquet. The Saturday morning program includes presentation of "Neuroblastoma in Childhood" by Dr. Robert C. Horn Jr., Henry Ford Hospital, Detroit, and a panel discussion, "A Proposed Blood Exchange Program."

Philadelphia

Frank Wister Thomas Professorship.—The University of Pennsylvania School of Medicine announces the establishment of the Frank Wister Thomas Professorship of Medicine, named for the late Dr. Thomas, an honor graduate in the school of medicine (class of 1880), who died in 1928 after having practiced medicine in Philadelphia for nearly 50 years. Dr. Francis C. Wood, chairman of the department of medicine, will be the first to hold the new professorship. Funds for the establishment of the chair were provided in the will of Dr. Thomas' widow, who also specified that "the head or chief professor of medicine at the Medical School" should occupy the chair. Dr. Wood has been associated with the medical faculty at Pennsylvania since 1928. During World War II he served in India for two years as chief of medical service in the 20th General Hospital Unit, which was organized at the University of Pennsylvania. He is a director of the Philadelphia County Medical Society.

SOUTH CAROLINA

Society News.—A joint meeting of the North Carolina Eye, Ear, Nose, and Throat Society and the South Carolina Society of Ophthalmology and Otolaryngology will be held at the Columbia Hotel in Columbia, Sept. 12-14. Guest speakers on ophthalmology will be Drs. Edward W. D. Norton and Frank D. Carroll, New York, and Dr. William B. Clark, New Orleans.

Piedmont Seminar.—The annual meeting of the Piedmont Postgraduate Seminar will be held at Clemson House Sept. 14-15. Out-of-state speakers will include Drs. John R. McCain and Edgar F. Fincher, Emory University, Ga.; Drs. Albert Vander Kloot, Anton M. Pantone, and Roger A. Harvey, Chicago; Dr. George D. Page, Charlotte, N. C.; and Dr. Bertram E. Sprofkin, Nashville, Tenn. Dr. Vander Kloot will discuss "Congestive Heart Failure" at the banquet Wednesday, and Dr. Harvey will deliver the Rose E. Romer Lecture at the Thursday banquet.

WASHINGTON

State Medical Meeting in Seattle.—The 66th annual session of the Washington State Medical Society will convene in Seattle Sept. 11-14 under the presidency of Dr. M. Shelby Jared, Seattle. Dr. Jared's presidential address Tuesday, 11 a. m., will be followed by a discussion of "Medicine, Legislation, and the Law" by C. Joseph Stetler, LL.M., Chicago, Director, A. M. A. Law Department. The annual banquet and dance (dress optional) will be held Tuesday. The public relations luncheon Wednesday noon will be addressed by Governor Arthur B. Langlie and by Dr. Elmer Hess, Erie, Pa., President of the American Medical Association, whose subject will be "How to Live Your Ethics." The president's reception will be held at 6:30 p. m. Dr. George N. Aagaard, Seattle, dean of the University of Washington School of Medicine, will address the house of delegates on medical school problems. Dr. William B. Bean, head, department of medicine, State University of Iowa College of Medicine, Iowa City, is scheduled to open the scientific sessions on Tuesday with "Recent Setbacks in Medicine" and to begin the Wednesday sessions with "Clinical Significance of Vascular Changes in the Skin and Mucous Membranes." Dr. Walter C. MacKenzie, department of surgery, University of Alberta Faculty of Medicine, Edmonton, Alberta, Canada, will open the Tuesday afternoon session with "Why Do Inguinal Hernias Recur?" and the Wednesday afternoon program with "Stop—Don't Operate!" There will be a no-host family dinner on Sunday at 6:30 p. m. Monday has been reserved for a salmon fishing derby (4:30 a. m., Ray's Boat House), the annual golf tournament (8:30 a. m., Seattle Golf Club), and the Sportsmen's Banquet (6:30 p. m., Seattle Golf Club). The woman's auxiliary, meeting simultaneously, will hold its annual luncheon Tuesday at 12:30 p. m. Addresses will be delivered by the national president, Mrs. Mason G. Lawson, Little Rock, Ark., and by Dr. Hess.

HAWAII

Report on Public Health.—According to the department of health, 1954 was the first year in which no deaths from tetanus occurred in the territory of Hawaii. The annual report indicates that 41 years have passed without a case of smallpox; 9 years without a death from diphtheria (only one case was reported for 1954); and 8 years without a death from typhoid fever (5 consecutive years without a single case). The tuberculosis rate of 9.3 showed a slight rise over the record low of 8.9 in 1953. Twenty new cases of leprosy (Hansen's disease) were confirmed, but only 10 patients needed isolation and the other 10 were granted outpatient status. Only seven maternal deaths occurred during the year. Of the 16,191 live births, the infant mortality rate was 22.4 per 1,000. Almost half the infant deaths were due to prematurity. Both maternal and infant death rates were lower than the national average.

GENERAL

Medical Examiner Staff Needed in Florida.—By recent act of the Florida State Legislature, a medical examiner's system has been established in Dade County effective Oct. 1. Funds have been provided for (1) employment of a full-time medical examiner, two part-time pathologists as assistant medical examiners, a toxicologist, secretaries, and other necessary personnel and (2) construction and equipment of a morgue and laboratories. Applicants for the position of chief medical examiner should address: Dr. Charles C. Hillman, Jackson Memorial Hospital, Miami, Fla.

Research Fellowship in Israel.—Applications are invited for the award of the Max and Rebecca Schrire Medical Research Fellowship (about $1,112) to a postgraduate student for research in medicine, with particular stress on ophthalmology, to be carried out at the Hebrew University in Jerusalem. Applications, containing biographical data, a brief outline of the proposed research project, and details on previous work, if any, should be forwarded to the Office of the Dean, The Hebrew University-Hadassah Medical School, P. O. B. 1255, Jerusalem, Israel, not later than Oct. 1, 1955.

Laurentian Hormone Conference.—The Laurentian Hormone Conference of the American Association for the Advancement of Science will hold its annual meeting at the Hotel Stanley, Estes Park, Colo., Sept. 11-16. The 14 presentations will include:

Biosynthesis and Metabolism of Thyroid Hormone, J. Roche, College de France, Paris, France.
Biosynthesis of the Sterols and Steroid Hormones, with Particular Reference to the Estrogens, R. D. H. Heard, McGill University School of Medicine, Montreal, Canada.
Male Sex Hormone and Its Role in Reproduction, Thaddeus Mann, University of Cambridge, England.

Uniform Sales Swindle.—Physicians are warned that one Herschel L. Rhodus is apparently operating a "confidence game" involving the sale of professional uniforms. Representing himself as a salesman for garment manufacturers, Rhodus allegedly collects cash deposits and payments for orders on uniforms that are not forwarded to the manufacturers. Rhodus is described as about 40 years old; height, 6 feet; weight, 185 pounds; sandy hair; frequently using the nickname "Doc." Formerly of Philadelphia, he is believed to be currently operating in Connecticut. Word has been received that warrants for his arrest are held by the police departments of Belleville, Ill., and Summit, N. J., to whom information concerning him should be sent.

Workshop in Medical Writing.—The American Medical Writers' Association will offer a workshop in medical writing Oct. 1, from 8 a. m. to 12 noon, during the annual meeting at the Hotel Jefferson, St. Louis. Dr. Richard M. Hewitt, Rochester, Minn., will serve as coordinator. The following presentations will be made:

From First Draft to Printed Article, Paul L. Fisher, Ph.D., School of Journalism, University of Missouri.
Specific Devices for Increasing the Readership of Medical Articles, Stewart Harral, M.A., School of Journalism, University of Oklahoma.
Writing Magazine Articles for the Lay Reader, Theodore B. Peterson, Ph.D., School of Journalism and Communications, University of Illinois.

There is no charge to members of the A. M. W. A.; for others the fee is $5. Those who intend to enroll are invited, well in advance of the meeting, to send manuscripts of popular medical articles to Theodore Peterson, Assistant Professor, School of Journalism and Communications, University of Illinois, Urbana. He will criticize some of these manuscripts at the workshop.

Meeting on Pharmacology.—The American Society for Pharmacology and Experimental Therapeutics will hold a meeting and a symposium on the teaching of pharmacology at the State University of Iowa, Iowa City, Sept. 4-8. Monday will be devoted to the symposium, "The General Principles of Excitability of Cardiac Tissue and Their Pharmacological Control," with Dr. Gordon K. Moe, Syracuse, N. Y., as moderator. In the evening Dr. Douglas S. Riggs, Buffalo, will moderate a symposium on graduate teaching in pharmacology. A panel discussion, "Chemical Bonding and the Molecular Level of Drug Interaction," Tuesday, 2-4 p. m. and 8-10 p. m., will have as moderator Fred W. Schueler, Ph.D., Iowa City. In all, 150 papers will be presented.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Meeting of Obstetricians and Gynecologists.—The American Association of Obstetricians and Gynecologists will hold its 66th annual meeting at the Homestead, Hot Springs, Va., Sept. 8-10, under the presidency of Dr. Thaddeus L. Montgomery, Philadelphia. Presentations by invitation will include:

Analysis of 6,891 Hysterectomies for Benign Pelvic Disease (with Special Reference to the Safety of Routine Total Abdominal Hysterectomy), C. Gordon Johnson, New Orleans.
Experience with the Use of Radioactive Colloidal Gold in Treatment of Ovarian Carcinoma, William C. Keettel, Iowa City.
Complications of Pregnancy and Nutritional Status (Toxemias of Pregnancy), Harold C. Mack, Detroit.
Cesarean Section in Cincinnati, Ohio, 1950 Through 1954, Richard D. Bryant, Cincinnati.
Statistical Study of 12 Possible Factors Governing Postpartum Bleeding, Raymond A. Schwegler, Lawrence, Kan.

Thursday at 8:45 p. m. Dr. J. Chassar Moir of Oxford, England, will deliver the Joseph Price Oration. The presidential address is scheduled for Friday noon, and the banquet will be addressed at 7:30 that evening by the Hon. George C. Corson, Plymouth Meeting, Pa. The annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons Foundation, Inc., will be held at the Homestead at 2:30 p. m. Thursday.

CANADA

Meeting on General Practice.—The Ontario chapter, College of General Practice of Canada, will present a symposium on medical practice at the Royal York Hotel, Toronto, Sept. 22. The morning session, moderated by Dr. Sandford English, Fort Erie, Ontario, will include "Pitfalls in Diagnosis" by Dr. Ray F. Farquharson, Toronto; "Lesions of the Prostate" by Dr. Harry R. Newman, New Haven, Conn.; and "Advances in Cardiovascular Surgery" by Dr. Eric M. Nanson, Saskatoon. Dr. Peter A. Kinsey, Toronto, will serve as moderator for the following afternoon program: "Renal Disease in Children," Dr. Weston M. Kelsey, Winston-Salem, N. C.; "The Significance of Bleeding Late in Pregnancy," Dr. Kenneth T. MacFarlane, Montreal; and "Office Procedures in Proctology," Dr. Louis A. Buie, Rochester, Minn. Questions and panel discussion will follow both sessions. Wives of physicians are invited to attend the luncheon, 12:15 p. m. (Dr. Max Alexandroff, St. Catharines, Ontario, chairman), and reception, 5:30-6:30 p. m. The symposium will be cosponsored by Lederle Laboratories Division of North American Cyanamid Limited.

DEATHS IN OTHER COUNTRIES

Dr. Thomas Jeeves (Lord) Horder, physician to Queen Elizabeth II, died at his home in Petersfield, England, Aug. 13, after a heart attack. Dr. Horder had served as president of the Harveian Society of London, the Fellowship of Medicine, the Medical Society of London, the Eugenics Society, and the British Association of Physical Medicine and had been chairman of the British Empire Cancer Campaign, the Empire Rheumatism Council, and the Noise Abatement League.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Oct. 12-14. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago, Director.

Academy of Psychosomatic Medicine, Hotel Plaza, New York, Oct. 6-8. Dr. Ethan Allan Brown, 75 Bay State Road, Boston 15, Secretary.

American Academy for Cerebral Palsy, Claridge Hotel, Memphis, Tenn., Oct. 10-12. Dr. Robert A. Knight, 869 Madison Ave., Memphis 3, Tenn., Secretary.

American Academy of Neurological Surgery, The Homestead, Hot Springs, Va., Oct. 27-29. Dr. Eben Alexander Jr., Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Palmer House, Chicago, Oct. 3-6. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Executive Secretary.

American Association of Medical Record Librarians, LaSalle Hotel, Chicago, Oct. 3-7. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Director.

American Association of Nursing Homes, Hotel Muehlebach, Kansas City, Mo., Sept. 19-21. Mr. Ira O. Wallace, P.O. Box 366, New Castle, Ky., Secretary.

American Association of Obstetricians and Gynecologists, The Homestead, Hot Springs, Va., Sept. 8-10. Dr. Frank R. Lock, Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 27-29. Dr. James K. Stack, 700 N. Michigan Blvd., Chicago 11, Secretary.

American College of Gastroenterology, Edgewater Beach Hotel, Chicago, Oct. 24-26. Dr. Joseph Shaiken, 33 West 60th St., New York 23, Secretary.

American College of Hospital Administrators, Convention Hall, Atlantic City, N. J., Sept. 17-19. Mr. Dean Conley, 620 North Michigan Ave., Chicago 11, Executive Director.

American Dental Association, San Francisco, Oct. 17-20. Dr. Harold Hillenbrand, 222 East Superior St., Chicago 11, General Secretary.

American Fracture Association, Hotel Fontainebleau, Miami Beach, Fla., Sept. 19-22. Dr. Homer D. Junkin, Paris Hospital, Paris, Ill., Secretary.

American Heart Association, Yung Hotel, New Orleans, Oct. 22-26. Mr. Irving Hexter, 44 East 23d St., New York 10, Secretary.

American Hospital Association, Traymore Hotel, Atlantic City, N. J., Sept. 19-22. Dr. Edwin L. Crosby, 18 East Division St., Chicago 10, Director.

American Medical Writers' Association, Jefferson Hotel, St. Louis, Sept. 30-Oct. 1. Dr. Harold Swanberg, P.O. Drawer 110, Quincy, Ill., Secretary.

American Physiological Society Fall Meeting, Tufts College, Medford, Mass., Sept. 6-9. Dr. Allan C. Burton, Univ. of Western Ontario, London, Ont., Canada, Secretary.

American Roentgen Ray Society, Palmer House, Chicago, Sept. 20-23. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Anesthesiologists, Hotel Statler, Boston, Oct. 29-Nov. 3. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago 1, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Fall Meeting, State University of Iowa, Iowa City, Sept. 4-8. Dr. Carl C. Pfeiffer, Emory University School of Medicine, Emory University, Ga., Secretary.

American Society of Plastic and Reconstructive Surgery, Atlantic City, N. J., Sept. 25-30. Dr. Kenneth L. Pickrell, Duke Hospital Durham, N. C., Secretary.

Association of American Medical Colleges, New Ocean House, Swampscott, Mass., Oct. 24-26. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of American Physicians and Surgeons, Chicago, Oct. 7-8. Mr. Harry E. Northam, 185 N. Wabash Ave., Chicago 1, Executive Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 19-21. Dr. Henry B. Kirkland, P. O. Box 594, Newark, N. J., Secretary.

Central Association of Obstetricians and Gynecologists, Deshler-Hilton Hotel, Columbus, Ohio, Oct. 5-8. Dr. Edwin J. DeCosta, Suite 602, 116 S. Michigan Ave., Chicago 3, Secretary.

Central Neuropsychiatric Association, The Broadmoor, Colorado Springs, Colo., Oct. 20-22. Dr. Hamilton Ford, 112 North Boulevard, Galveston, Tex., Seceretary.

Clinical Orthopaedic Society, Skirvin Hotel, Oklahoma City, Sept. 30-Oct. 1. Dr. Marcus J. Stewart, 869 Madison Ave., Memphis, Tenn., Executive Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 10-15. Dr. Arthur H. Dearing, 203 N. Wabash Ave., Chicago 1, Executive Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Congress of Neurological Surgeons, Hotel Statler, Los Angeles, Oct. 27-29. Dr. Philip D. Gordy, 1007 Delaware Ave., Wilmington, Del., Secretary.

Delaware, Medical Society of, Delaware Academy of Medicine, Wilmington, Oct. 17-18. Dr. Norman L. Cannon, 621 Delaware Ave., Wilmington, Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, D. C., Oct. 10-12. Mr. Theodore Wiprud, 1718 M St., N.W., Washington 6, D. C., Executive Director.

Gerontological Society, Sheraton-Belvedere Hotel, Baltimore, Oct. 27-29. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 27-28. Dr. Barkley Beidleman, 1750 N. Palafox St., Pensacola, Fla., Secretary.

Indiana State Medical Association, French Lick Springs Hotel, French Lick, Oct. 16-19. Mr. James A. Waggener, 23 East Ohio St., Indianapolis 4, Executive Secretary.

Industrial Health Conference, Shamrock Hotel, Houston, Texas, Sept. 22-23. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Texas, Chairman.

Kansas City Southwest Clinical Society, Municipal Auditorium, Kansas City, Mo., Oct. 3-6. Dr. W. M. Kitchen, 306 E. Twelfth St., Kansas City 6e, Mo., Secretary.

Kentucky State Medical Association, Louisville, Sept. 27-29. Mr. J. P. Sanford, 620 S. Third St., Louisville, Executive Secretary.

Michigan State Medical Society, Pantlind Hotel, Grand Rapids, Sept. 26-30. Dr. L. Fernald Foster, 606 Townsend St., Lansing 5, Secretary.

Midwest Conference on Rheumatic Diseases, Henry Ford Hospital, Detroit, Oct. 5. Dr. J. J. Lightbody, 7338 Woodward Ave., Detroit 2, Medical Director.

Mississippi Valley Medical Society, Jefferson Hotel, St. Louis, Sept. 28-30. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Mississippi Valley Trudeau Society, Hotel Savery, Des Moines, Iowa, Oct. 14. Dr. Harold G. Curtis, Sunny Acres, Cuyahoga County Tuberculosis Hospital, Cleveland 22, Chairman, Program Committee.

Montana Medical Association, Baxter Hotel, Bozeman, Sept. 15-18. Mr. L. R. Hegland, P.O. Box 1692, Billings, Executive Secretary.

New Hampshire Medical Society, Mt. Washington Hotel, Bretton Woods, Sept. 29-Oct. 1. Dr. Warren H. Butterfield, 18 School St., Concord, Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Tex., Sept. 17. Dr. E. C. Bebb, Broad St., Wichita Falls, Tex., Chairman.

Oklahoma City Clinical Society Conference, Oklahoma City, Oct. 24-27. Dr. Charles E. Leonard, 512 Medical Arts Bldg., Oklahoma City 2, Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 24-27. Mrs. Anne K. Ramsey, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Oregon State Medical Society, Hotel Heathman, Portland, Sept. 28-Oct. 1. Dr. Richard R. Carter, 1020 S.W. Taylor St., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 18-23. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Postgraduate Assembly in Endocrinology and Metabolism, Indianapolis, Sept. 26-Oct 1. Dr. John J. Mahoney, Assistant Dean, Indiana University School of Medicine, 1040 W. Michigan St., Indianapolis 7.

Regional Meetings, American College of Physicians:

Jamestown, N. D., Sept. 10. Mr. E. R Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

Madison, Wis., Oct. 15. Dr. Howard Wakefield, 122 S. Michigan Ave., Chicago 3, Governor.

Society of General Physiologists, Marine Biological Laboratory, Woods Hole, Mass., Sept. 9-10. Dr. A. M. Shanes, National Institutes of Health, Bethesda 14, Md.

Southwestern Surgical Congress, Muehlebach Hotel, Kansas City, Mo., Sept. 5-7. Dr. C. M. O'Leary, 207 Plaza Court Bldg., Oklahoma City, Secretary.

Tennessee Valley Medical Assembly, Read House, Chattanooga, Tenn., Oct. 3-4. Dr. Harry E. Jones, 109 Medical Arts Bldg., Chattanooga 2, Tenn., Secretary.

The Constantinian Society, Sheraton-Park Hotel, Washington, D. C., Oct. 26-29. Dr. C. F. Shook, P. O. Box 1035-36, Toledo 1, Ohio, Secretary.

Tri-State Medical Society, Grim Hotel, Texarkana, Tex., Sept. 28-29. Dr. Karlton H. Kemp, 408 Hazel St., Texarkana, Ark., Secretary.

U. S. Chapter, International College of Surgeons, Convention Hall, Philadelphia, Sept. 12-15. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Union Bldg., Salt Lake City, Sept. 8-10. Mr. H. Bowman, 42 S. Fifth East St., Salt Lake City 2, Executive Secretary.

Vermont State Medical Society, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 29-Oct. 1. Dr. James P. Hammond, 337 South St., Bennington, Secretary.

Virginia, Medical Society of, Hotel Jefferson, Richmond, Oct. 16-19. Mr. Robert I. Howard, 105 West Franklin St., Richmond, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 11-14. Dr. Frederick A. Tucker, 1309 Seventh Ave., Seattle 1, Secretary.

Western Association of Railway Surgeons, Las Vegas, Nev., Sept. 22-24. Dr. Leo L. Stanley, 1322 Fifth Ave., San Rafael, Calif., Secretary.

FOREIGN AND INTERNATIONAL

Canadian Society for the Study of Fertility, Royal York Hotel, Toronto, Ont., Canada, Oct. 6-8. Dr. Earl R. Plunkett, 469 Waterloo St., London, Ont., Canada, Secretary.

Congress of International Association of Limnology, Helsinki, Finland, July 26-Aug. 7, 1956. For information address: Dr. H. Luther, Snellmansgatan 16 C 36, Helsinki, Finland.

Congress of International Association of Logopedics and Phoniatrics, Barcelona, Spain, Sept. 3-7, 1956. Dr. J. Perello, Provenza 319, Barcelona 9, Spain, Secretary-General.

Congress of International Society of Hematology, Hotel Statler, Boston, Mass., U.S.A., Sept. 3-8, 1956. Dr. W. C. Moloney, 39 Bay State Road, Boston, Mass., U.S.A., Secretary.

Congress of International Society for Research on Anesthesia, Miami Beach, Fla., U.S.A., Mar. 12-15, 1956. For information write: Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland 12, Ohio, U. S. A.

Congress of International Union of Railway Medical Services, Dubrovnik, Yugoslavia, Sept. 19-24. Dr. Jovanovic, Head Office, Yugoslav Railway, Belgrade, Yugoslavia, President.

Congress of International Union Against Venereal Diseases, Naples, Italy, Sept. 25-28. For information address: Prof. Monacelli, University of Naples, Dept. of Dermatology, Naples, Italy.

Congress of Latin Society of Ophthalmology, Madrid, Spain, April 24-28, 1956. For information address: Dr. Costi, Montalban 3, Madrid, Spain.

International Academy of Legal and Social Medicine, Plenary Conference, Genoa, Italy, Oct. 13-17. Prof. Domenico Macaggi, Institut de Medicine legale, Universite de Genes, Genes, Italy, President.

International Conference of Medical Librarians and Reference Librarians, University Hall, Brussels, Belgium, Sept. 10. For information address: Miss Ch. de Looze, Librarian ℅ Oeuvre Nationale Belge de Defense contra la Tuberculose, 56, rue de la Concorde, Brussels, Belgium.

International Congress of Allergology, Rio de Janeiro, Brazil, S. A., Nov. 6-13. Dr. Bernard N. Halpern, 197 boulevard St. Germain, Paris 7e, France, Secretary General.

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. Fenton, National Research Council, Division of Anthropology and Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress of Criminology, London, England, Sept. 11-18. For information write: Dr. Carroll, 28 Weymouth St., London, W.1, England.

International Congress of European Society of Haematology, Freiburg i,Br., Germany, Sept. 20-24. Prof. Dr. L. Heilmeyer, Hugstetter Strasse 55, Freiburg i,Br., Germany, Chairman.

International Congress for the History of Science, Florence and Milan, Italy, Sept. 3-10, 1956. Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy, Secretary-General.

International Congress of Hydatid Disease, Athens, Greece, Sept. 14-18, 1956. Prof. B. Kourias, Croix-Rouge Hellenique, 1 rue Mackenzie King, Athens, Greece, Secretary-General.

International Congress of Internal Medicine, Madrid, Spain, Sept. 19-23, 1956. Dr. J. C. De Oya and Dr. J. Gimena, Hostaleza No. 90, Madrid, Spain, Secretaries.

International Congress of International College of Surgeons, Buenos Aires, Argentina, S. A., Nov. 19-24, 1956. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress of International Society of Bronchoesophagology, Buenos Aires, Argentina, S. A., Oct. 28-29. Dr. Juan Carlos Arauz, Cangallo 4015, Buenos Aires, Argentina, S. A., Secretary General.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* New York City, Oct. 23-27. *Written.* Various locations in United States and Canada, July 20, 1956. Final date for filing application is Jan. 20. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: *Oral.* Washington, D. C., Oct. 14-16. Final date for filing application was March 15. Sec., Dr. B. M. Kesten, One Haven Ave., New York 32, N. Y.

American Board of Internal Medicine: *Oral.* Portland, Ore., Sept. 14-16; Chicago, Nov. 30-Dec. 1. *Subspecialties. Cardiovascular Disease.* Chicago, Nov. 30. The closing date for acceptance of applications for gastroenterology was Feb. 1, and for cardiovascular disease the closing date was June 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* New Haven, November. Oral examinations given in Spring and Fall. Final date for filing application for the Spring examination is October 1; for the Fall examination April 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Written Examination and submission of Case Reports. Part I.* Various locations in United States and Canada, Feb. 3, 1956. Final date for filing application is Oct. 1. *Oral and Pathological Examinations. Part II.* Chicago, May 11-20, 1956. Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Practical Examination.* Chicago, Oct. 3-7. Final date for filing application for 1955 practical examination was July 1, 1954. *Written.* January, 1956. Final date for filing application was July 1. *Practical Examination.* St. Louis, Oct. 20-25, San Francisco, June 18-23. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral.* Jan. 26-27. Final date for filing application was Aug. 15. *Written.* Various cities, April 1956. Final date for filing application is Nov. 30. Sec., Dr. Harold A. Sofield, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 3-7. Final date for filing application is April. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: *Written and Practical.* Chicago, Oct. 6-8. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago.

American Board of Pediatrics: *Oral.* Chicago, Oct. 7-9; and Washington, D. C., Dec. 2-4. Admin. Sec., Mrs. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation. *Parts I and II.* Chicago, June 16-17. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Philadelphia, Sept. 22-24. Corres. Sec., Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *Certification in Public Health.* Kansas City, Mo., Nov. 10-12. Sec.-Treas., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore 5.

American Board of Proctology: *Part II.* Philadelphia, Sept. 17. Sec., Dr. Stuart T. Ross, 131 Fulton Ave., Hempstead, N. Y.

American Board of Psychiatry and Neurology: San Francisco, Oct. 17-18; New York City, December, Philadelphia, April 16-18, 1956. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: Chicago, Dec. 4. Final date for filing applications for the fall examination was July 1. Candidates who will complete their training by Dec. 31 will be eligible to appear for this examination. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Centers throughout the United States, in Europe and in the Far East, Oct. 26 and March 28. Closing date for the October examination was July 1 and for the March examination is December 1. *Part II.* Buffalo, Sept. 26-27; Chicago, Oct. 27-28; New York City, Nov. 14-15; St. Louis, Dec. 12-13; New Orleans, Jan. 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, Mar. 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

The Board of Thoracic Surgery: *Written.* Various Centers, Sept. 9. Final date for filing applications was July 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Ave., Detroit 2.

MAGAZINE-TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Sept. 5

NBC-TV, 9 p. m. EDT. "Medic" will present "All the Lonely Night," a case history of a young woman whose deep-rooted emotional problems finally lead to a physical ailment—an ulcerated colon.

Wednesday, Sept. 7

NBC-TV, 11 a. m. EDT. "Home" features a report on "Medical and Health News" with Howard Whitman.

MAGAZINES

U. S. News & World Report, Aug. 26, 1955

"What You Should Know About Drinking," by Ralph A. Habas

Extracts from a book, "How to Live Without Liquor," in which the author seeks to answer questions about the drinking problem. In an accompanying statement, Dr. W. W. Bauer, Director of the American Medical Association's Bureau of Health Education, calls the presentation "scientific yet simple, compassionate yet uncompromising, realistic yet strongly encouraging."

Family Weekly Magazine, Aug. 28, 1955

"Let's Look at Hospital Costs," by Hal Levinson

"Hospital care in the U. S. today is the best in the world; and its cost is not nearly as high, comparatively, as the cost of other goods and services in this inflationary era." The article explains the cost of room accommodations, the operating room, laboratory work, and drugs.

Good Housekeeping, September, 1955

"Send for an Ambulance!" by Samuel Grafton

"Several thousand ambulance organizations in this country, public and private, stand ready around the clock to perform one of the most frightening tasks that can fall to anyone—that of moving a sick or injured person from home to street to hospital." A description of the work of ambulance crews, the equipment used, and suggestions on what the reader should do if it is necessary to call an ambulance.

Parents' Magazine, September, 1955

"Is That Stomach Ache Appendicitis?" by Constance Foster

"Operated on in time appendicitis is no longer the danger it was. But too late is still too late. So familiarize yourself with the symptoms described here, be alert, not panicky, and call your doctor."

"What to Tell Your Daughter," by Margaret Albrecht

Advice on what a mother should tell her daughter about menstruation.

Cosmopolitan, September, 1955

"The Miracle Makers," by Don Short

Doctors at Brooke Army Medical Center have won unbelievable victories in their war against burns.

"Headaches," by Lawrence Galton

The author reports current treatments for severe headaches. For migraine headaches, he mentions use of ergotamine tartrate with caffeine, injections of Dramamine, a new suppository called Pentergot, and reserpine. For tension headaches, new treatments available are Pentergot, Fiorinal, Miltown, reserpine, and Mephate.

DEATHS

Bernecker, Edward Martin ⊕ New York City; born in Seward, Neb., March 13, 1892; the Hahnemann Medical College and Hospital, Chicago, 1915; interned at the Metropolitan Hospital in Welfare Island, where he was resident surgeon in 1917, deputy medical superintendent in 1920, and later medical superintendent; medical superintendent of the Kings County Hospital in Brooklyn from 1935 to 1937, when he became general medical superintendent of the department of hospitals in the City of New York, serving until 1942; from 1942 to 1948 commissioner of hospitals; since January, 1949, hospital administrator of New York University-Bellevue Medical Center; served overseas during World War I; chief of the emergency medical service, New York City, from 1942 to 1945; fellow of the American College of Hospital Administrators and New York Academy of Medicine; member of the New York State Hospital Association and the American Hospital Association; died in the New York University Hospital June 27, aged 63, of a heart attack.

Hunt, Preston, Texarkana, Texas; Atlanta College of Physicians and Surgeons, 1901; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association in 1938 and 1940; past-president of the State Medical Association of Texas and the Bowie County Medical Society; past-president of the Lions Club; on the staff of the Texarkana Hospital; died in Pampa July 10, aged 89.

Irwin, George Allan Lyall, La Jolla, Calif.; M.B., 1912, and M.D., 1921, Queen's University Faculty of Medicine, Kingston, Ontario, Canada; died in Southampton, N. Y., June 27, aged 67, of coronary occlusion.

Jackson, Walter B. ⊕ Waxahachie, Texas; College of Physicians and Surgeons, Dallas, 1907; past-president of the Ellis County Medical Society; formerly city health officer at Alvarado and also served in that capacity in Waxahachie; died June 29, aged 76, of congestive heart disease.

Jacobson, Julian C. ⊕ Santa Cruz, Calif.; University of Minnesota Medical School, Minneapolis, 1937; past-president of the Santa Cruz County Medical Association; served during World War II; on the staffs of the Santa Cruz and Sisters hospitals; died July 1, aged 49, of coronary occlusion.

Jardini, Alessandro S., Los Angeles; Regia Università di Torino Facoltà di Medicina e Chirurgia, Italy, 1902; served in the Italian Army during World War I; on the staff of the French Hospital; died July 9, aged 77, of intestinal obstruction.

Jefferies, Charles A., Gaffney, S. C.; Medical Department of Tulane University of Louisiana, New Orleans, 1890; died in the Mountain Sanitarium and Hospital in Fletcher, N. C., June 27, aged 87, of cerebral arteriosclerosis.

Kelly, Raymond Martin ⊕ Chicago; Loyola University School of Medicine, Chicago, 1916; a medical officer during World War I; served on the staff of St. Anne's Hospital, where he was first president of the hospital board; died July 15, aged 64, of rheumatic heart disease.

Knowlton, Florence Emerson Honey, Pacific Grove, Calif.; Tufts College Medical School, Boston, 1920; died July 12, aged 65.

Lampson, Edward Rutledge ⊕ Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York City, 1896; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; past-president of the Hartford County Medical Society and the Hartford Medical Society; for many years on the staff of the Hartford Hospital, where he died June 24, aged 87, of coronary thrombosis.

Lombardo, Theodore Roosevelt ⊕ Brooklyn, N. Y.; Long Island College of Medicine, Brooklyn, 1936; served during World War II; for many years on the medical staff of St. Mary's Hospital and Brooklyn College; died in St. Vincent's Hospital July 20, aged 45.

Love, Thomas Stafford ⊕ Dallas, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1920; specialist certified by the American Board of Otolaryngology; served during World War I; formerly on the faculty of Southwestern Medical School of the University of Texas; on the staffs of Baylor University Hospital, Medical Arts Hospital, Parkland Hospital, and Texas Scottish Rite Hospital for Crippled Children; died June 26, aged 59, of myocardial infarction.

Lyon, James Ira ⊕ Edmond, Okla.; Kansas City (Mo.) Medical College, 1892; past-president of the board of education; died in the Wesley Hospital, Oklahoma City, July 11, aged 85, of cerebral thrombosis.

Merkel, George Albert ⊕ Minersville, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1904; an associate member of the American Medical Association; president of the First National Bank and Home Building and Loan Association; on the staff of the Warne Hospital, Pottsville, where he died May 18, aged 73, of intestinal obstruction.

Miltenberger, Val E. ⊕ Lieutenant colonel, U. S. Army, retired, Kirksville, Mo.; St. Louis University School of Medicine, 1904; entered the U. S. Army in 1917; became a lieutenant colonel in April, 1937; retired Nov. 30, 1937; returned to active duty from February, 1943, to Jan. 31, 1945; died in Albuquerque, N. Mex., July 14, aged 74.

Osborn, Howard A., Grand Rapids, Mich.; Detroit College of Medicine, 1906; served during World War I; formerly practiced in Detroit, where he was on the staff of the Harper Hospital; for many years on the staff of the Burleson Hospital; died in the Butterworth Hospital July 19, aged 72.

Pargen, Thomas Houston, Austin, Texas; Georgetown University School of Medicine, Washington, D. C., 1926; member of the Southern Psychiatric Association and the American Psychiatric Association; served during World War II; for a time a member of the staff of Austin State School; recently served on the staff at McKnight State Sanatorium in Sanatorium; died in Brackenridge Hospital July 8, aged 52, of congestive heart disease.

Perry, Seth Bridgman, Hopewell, Va.; Medical College of Virginia, Richmond, 1914; member of the Medical Society of Virginia; for many years vice-mayor and city councilman; died June 21, aged 67, of a heart attack.

Perusse, George Louis ⊕ Chicago; Jenner Medical College, Chicago, 1908; member of the Industrial Medical Association; at one time superintendent of the Michael Reese Hospital; on the staffs of the Columbus Memorial Hospital and the Grant Hospital, where he died July 15, aged 79, of calcified aortic stenosis and arteriosclerosis.

Pond, Bernard Wesley ⊕ Newton, Mass.; Harvard Medical School, Boston, 1901; died in the Newton-Wellesley Hospital Aug. 1, aged 81, of heart disease.

Powell, Daniel Drury, Jackson, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1953; interned at the Charity Hospital of Louisiana in New Orleans; resident at the Huey P. Long Charity Hospital in Pineville, La.; died July 20, aged 28, of coronary occlusion.

Reinsch, Frank, Ashton, Iowa; Chicago College of Medicine and Surgery, 1917; at one time county coroner; served during World War I; for many years a member and president of the school board; died in Osceola (Iowa) Hospital July 5, aged 61, of cancer.

Renshaw, John B., Glendale, Calif.; Medical Department of Tulane University of Louisiana, New Orleans, 1888; died June 27, aged 88, of cancer.

Reynolds, John Andrew ⊕ Springfield, Mass.; Long Island College Hospital, Brooklyn, 1922; served on the staffs of the Wesson Memorial Hospital and the Springfield Hospital, where he died June 28, aged 62, of arteriosclerotic heart disease.

Robbins, Agnes Louise ⊕ Kansas City, Kan.; University of Kansas School of Medicine, Kansas City, 1945; interned at St. Margaret's Hospital; member of the American Academy of General Practice; on the staffs of St. Margaret's and Providence hospitals and the Bethany Hospital, where she died July 15, aged 47.

Rose, James Madison, Olive Hill, Ky.; University of Louisville Medical Department, 1909; member of the Kentucky State Medical Association; past-president of the Carter County Medical Society; served as mayor of Olive Hill, and as state senator from 1928 to 1936; president of the People's Bank of Olive Hill; member of the board of regents of Morehead (Ky.) State College; died July 5, aged 69, of a heart attack.

Rosenthal, Julius Mordecai ⊕ Monticello, N. Y.; University and Bellevue Hospital Medical College, New York City, 1906; member of the American College of Chest Physicians; an associate member of the American Medical Association; served on the board of the Monticello Hospital; died in Miami Beach, Fla., July 10, aged 77.

Ross, Floyd Freeland ⊕ Berkeley, Calif.; Howard University College of Medicine, Washington, D. C., 1927; on the staff of the Herrick Memorial Hospital; died July 6, aged 54, of heart disease.

Rowe, Mary Virginia Copeland, Marion, N. C.; Tulane University of Louisiana School of Medicine, New Orleans, 1939; member of the Medical Society of the State of North Carolina; interned at the Guilford County Sanatorium in Jamestown and the Crawford W. Long Memorial Hospital in Atlanta, Ga.; died in the Marion General Hospital May 23, aged 40, of pancreatitis and chronic cholecystitis.

Rucks, William Ward ⊕ Oklahoma City, Okla.; University of Nashville (Tenn.) Medical Department, 1897; served during World War I; member of the Association of Life Insurance Medical Directors of America; formerly medical director of the Home State Life Insurance Company; co-founder and on the staff of the Wesley Hospital, where he died July 14, aged 80, of myocardial infarction.

Saunders, Griffin Augustus ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1914; for 25 years served with the city department of health; on the staff of the Mercy-Douglas Hospital for many years; died in the Hospital of the University of Pennsylvania June 25, aged 66, of carcinoma of the tongue with metastases.

Schmidt, William Francis ⊕ Philadelphia; The General Medical College, Chicago, 1923; on the staffs of the Frankford and Episcopal hospitals; died in the Jeanes Hospital May 28, aged 71, of cerebral thrombosis.

Seely, Richard Henry ⊕ Trenton, N. J.; Jefferson Medical College of Philadelphia, 1945; specialist certified by the American Board of Ophthalmology; served during World War II; formerly a resident in ophthalmology at the Wills Hospital in Philadelphia, where he was later an associate ophthalmologist; interned at St. Francis Hospital, where he was an associate ophthalmologist, and where he died July 17, aged 34, of chronic lymphocytic leukemia.

Sickerman, Clairmont William ⊕ Indianapolis; University of Louisville (Ky.) School of Medicine, 1933; on the staff of Methodist Hospital; died June 11, aged 52, of coronary occlusion.

Sleeter, Robert William ⊕ Medford, Ore.; University of Oregon Medical School, Portland, 1937; interned at Sacramento (Calif.) County Hospital; served during World War II; died in Arco, Idaho, July 14, aged 43, of coronary occlusion.

Sostek, Samuel Bertram, Malden, Mass.; Boston University School of Medicine, 1937; member of the Massachusetts Medical Society; interned at the Jewish Hospital in Brooklyn, N. Y.; served a residency at the Boston City Hospital; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; served during World War II; died in the Massachusetts Memorial Hospital in Boston May 1, aged 45.

Summers, James Arthur ⊕ Little Rock, Ark. (licensed in Arkansas in 1903); for 22 years health officer of Pulaski County; at one time health officer of North Little Rock; died July 7, aged 74, of myocardial infarction and cancer of the prostate.

Tompkins, Archibald, Savannah, Ga.; Meharry Medical College, Nashville, Tenn., 1911; died in the Charity Hospital June 7, aged 70, of cerebral hemorrhage, hypertension, and chronic interstitial nephritis.

Tracy, Elizabeth Roberts Cahoon, Sanford, Fla.; New York Medical College and Hospital for Women, Homeopathic, New York City, 1900; died in Deland July 23, aged 91, of hypostatic pneumonia and myocardial degeneration.

Walker, Arthur Bruce, Lincoln, Neb.; John A. Creighton Medical College, Omaha, 1906; died in St. Elizabeth Hospital July 4, aged 77, of cerebral thrombosis, hypertension, and arteriosclerosis.

Walker, John Keasbey ⊕ Haverford, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; an associate member of the American Medical Association; died in the Bryn Mawr (Pa.) Hospital June 18, aged 77, of cerebrovascular disease.

Wallingford, William H., Princeton, W. Va.; Hospital College of Medicine, Louisville, Ky., 1907; past-president of the Mercer County Medical Society; served as chief surgeon at the Princeton Hospital, which he established; died in Salem, Va., July 18, aged 75, of pneumonia and arteriosclerotic heart disease.

Watkins, Benjamin F., Jackson, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1905; died in the Veterans Administration Hospital in Atlanta May 11, aged 74, of uremia and chronic pyelonephritis.

White, Thomas Watson, Houston, Texas; University of Texas School of Medicine, Galveston, 1898; veteran of the Spanish-American War; died July 4, aged 79, of arteriosclerosis and hypertension.

Wood, Joseph Benjamin, Marietta, Ga.; University of Georgia Medical Department, Augusta, 1898; died May 29, aged 89, of pneumonia and hypertension.

Wright, Daniel Paul, Patton, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1913; died in the Southeast Missouri Hospital, Cape Girardeau, May 17, aged 76, of acute coronary occlusion.

CORRECTION

Krakowski, Joseph.—The obituary of Dr. Adam Joseph Krakowski (The Journal, July 30, 1955, page 1186), was erroneous. The physician referred to was Dr. Joseph Krakowski of Staten Island, N. Y., who graduated from the University of Poznan in Poland in 1933, was a resident physician on the staff of the Richmond Memorial Hospital, and died May 12, aged 48, of perforated duodenal ulcer.

BELGIUM

Complications of Gastrectomy.—At a meeting of the Belgian Gastroenterological Society in November, Godart and Van Lerberghe said that after gastrectomy anemia and the dumping syndrome were well known. In a series of 40 patients who had a dumping syndrome, each patient was examined with ordinary barium and with sweetened, lactated barium to induce the dumping syndrome. The authors concluded that in all patients the motor disturbances are associated with stomal incontinence and a dilatation of the jejunum. With endoscopy the development of a dilatation due to hypotonia rather than to internal hypertension is seen. The authors saw no dilatation in the jejunum on radiography, but they did see it in the ileum. Thickening of the folds, usually attributed to jejunitis, seemed to them to be caused by hypotonia of the mucosa. This concept was supported by the fact that dilatation was produced with lactated barium but not with plain barium. The ileum is hypertonic and segmented. This hypotonia followed by hypertonia determines the speed of transit, which is always rapid. Bargen explained this as follows: if peristalsis encounters a hypotonic loop, churning and arrest occur. This also explains why patients with gastrectomy rarely have diarrhea. In the dog, electric stimulation of the proximal end of the stomach causes jejunal hypotonia and ileal hypertonia. To avoid this one must section the sympathetic nerve, and not the vagus. Excitation can also explain chronic hypotonia in man.

Fight Against Poliomyelitis.—At the March meeting of the Belgian Health and Social Medicine Society, Dr. Recht pointed out that it is difficult to organize a program for the control of poliomyelitis because of the unpredictable characteristics of the epidemic and the scarcity of prodromal symptoms. In setting up such a program it was decided that four university centers with two extra centers, one at Anvers and one at Charleroi, would be better than one. The country now has 35 iron lungs, 7 thoracic cuirasses, and 14 Engström respirators. In 1950 the Inter-University Foundation for the Treatment of Virus Diseases and Poliomyelitis was created, and in 1954 the Princess Josephine Charlotte Center of Studies was started. Financial assistance for victims of poliomyelitis is provided by the Sickness-Disability Insurance and the Public Welfare Commission. Since April 10, 1952, a special fund covers treatment expenses of patients with poliomyelitis. In July, 1950, the National Radiodiffusion Institute launched a movement called the "Chain of Happiness." These funds go for the help of children with poliomyelitis over a period of several years, either by paying for their treatment or helping to buy prostheses. In 1943 the National Defense League Against Poliomyelitis was started to coordinate research and direct aid to patients.

Antipoliomyelitic Antibodies.—At a meeting of the Royal Academy of Medicine in 1954, Quersin-Thiry and Dekegel stated that 42% of the children under 10 in Belgium have antibodies against the three types of poliomyelitis virus and 90% of them have antibodies against at least one type. After the age of 10, immunization proceeds slowly and the situation is hardly changed up to the late 20's. Thus, between 10 and 17% of persons under 30 have no immunity to any type of poliomyelitis virus. There is little difference between the types of virus regarding the frequency with which persons become immunized, but the three types are not equal with respect to the intensity of this immunization. Among persons with antibodies against type 3 virus, 60% have an elevated serum titer, while such a titer is found in only 22% of those immunized against type 2 and in 33% of those with anti-type 1 antibodies. The antibody titer is generally less in persons aged from 5 to 29 years than in adults or children under 5, except for those of less than 6 months, in whom it is very low.

BRAZIL

Carcinoma of the Liver.—In the *Annals of the Medical School of Recife,* Dr. Adonis Carvalho reviewed 2,797 autopsies performed at the department of pathology of the University of Recife and concluded that the incidence of primary carcinoma of the liver was 0.57% or similar to that found in the United States and Europe. There appears to have been no increase in the incidence of this disease in the last 10 years. The incidence was greatest in the age group of 40 to 49 years, which suggests that the onset of the disease is earlier here than in other countries. The ratio of men to women affected was 4:1. The relation of hepatic cancer to cancers in other parts of the body is a little higher here than in the United States and Europe and lower than in Africa. The incidence of this disease in persons with hepatic cirrhosis is greater than in persons without hepatic cirrhosis. No relation was found between schistosomiasis and primary carcinoma of the liver. Liver cell carcinoma is almost four times as frequent as bile duct carcinoma. Hepatomegaly and splenomegaly are almost always present in patients with hepatic cancer. The starting point is often the right lobe, but intrahepatic metastasis occurred in practically every case. The extrahepatic metastases were found most often in the lungs and the spleen.

Postoperative Care.—Dr. Fernando Paulino reported in *Revista Brasileira de Cirurgia* (vol. 29, April, 1955) a series of 200 patients subjected to major operations, mostly in the upper gastrointestinal tract, to whom postoperatively he gave intravenous infusions of dextrose, amino acids, alcohol, electrolytes, and vitamins. More than 1,600 liters of this solution were injected, and no undesirable reactions were observed. The solution provides about 1,000 calories per liter. Thus, sufficient calories can be given without overhydration of the patient. The intravenous use of alcohol did not interfere with the patient's water, sodium, and potassium balance or with the nonprotein nitrogen level, and positive nitrogen balance was maintained by parenteral administration of therapy alone. Urinary excretion of glucose seldom occurred, and when it did occur it was corrected by reducing the speed of the injection. The author concluded that positive nitrogen balance is a definite aid to the recovery of patients subjected to major operations.

ENGLAND

Comet Aircraft Disaster Autopsies.—A report by Stewart and Whittingham (*Lancet* 1:1136, 1955) of the postmortem findings in the bodies recovered after the two Comet aircraft disasters over the Mediterranean Sea in 1954 includes the findings of the experimental work carried out on animals as an aid in interpreting the cause of death of the victims of the crashes. At the time of the disasters, both Comets had reached an altitude of about 30,000 ft. during the initial climb. At this height the air pressure inside the cabin is about 7.5 lb. per square inch above that prevailing outside. All but 5 of the 19 bodies examined had antemortem fractures of the skull, and 15 had similar injuries of the thoracic cage, mostly of exceptional severity. Spinal fractures and costovertebral dislocations were common. Limb fractures, found in 13 bodies, were predominantly sustained post mortem. Grave internal injuries were present in all the bodies, even in those with little external injury. Thus, hemothorax, of 0.3 to 2 liters, was present in 13, and the lungs were severely damaged in all cases. In no case was there evidence of drowning. Hemoperitoneum (up to 1 liter) was present in 14 and hepatic laceration in all cases. Tears of the spleen were found in only five and severe injury to the lungs was found in all cases. Macroscopically lung injury consisted of congestion, bruising, laceration, pulping, and areas of ballooning, with subpleural bullae. Microscopically the findings were traumatic

The items in these letters are contributed by regular correspondents in the various foreign countries.

emphysema, hemorrhage, vascular engorgement, and fat embolism. From an analysis of the autopsy findings, it was concluded that in all probability the pulmonary lesions were not caused by an explosion, the reasons being: (1) in none of the bodies recovered (including that of a child aged 10 years) did the subpleural hemorrhages show a pattern of rib markings; (2) the lungs of all had much the same appearance, whereas in explosion, a significant variation in the degree of injury might be expected, people seated near the source being most severely affected; (3) in no case was blood or froth present in the nose, mouth, or elsewhere in the upper respiratory passages; (4) none of the bodies had skin lesions attributable to peppering with metallic fragments or other missiles; and (5) none had burns such as are caused by naked flame. Also, there was no evidence of a bomb explosion or of any fire inside the cabin of the aircraft.

An interesting difference between the bodies recovered from the two disasters was noted in the skin. In the bodies recovered from the Elba crash the skin lesions, called "burns" for convenience, showed histological evidence of tissue destruction and affected predominantly clothed areas; however, no evidence of exposure to flame or searing temperatures was seen. In the bodies recovered from the Naples crash the skin lesions, called "darkening" for convenience, involved exposed skin only, and again, there was no evidence of exposure to flame or searing temperatures. It was concluded that the Elba bodies were subjected to postmortem scalding of the skin as a result of fire starting after they had fallen into an area covered by a kerosene film. The Naples bodies showed no scalds but instead a postmortem darkening of the pigment (the Meirowsky phenomenon) as the result of exposure to bright sunlight.

The final reconstruction of the course of events from the medical evidence is that the injuries were inflicted in three distinct phases: in the aircraft, on impact with the sea, and while the bodies were floating in the water. The head injuries, certain abrasions, and at least some fractures of the thoracic cage were acquired in the aircraft as a result of an extremely violent upward and forward displacement of the seated occupants as a result of sudden cabin failure. This would be sufficient to cause death. As the aircraft disintegrated, all or most of the passengers were ejected and fell into the sea. All the available evidence indicates that forces generated by impact with a water surface after such a fall must cause grave injury to the internal organs. The nature of the internal injuries in the bodies recovered, including the pulmonary lesions, is consistent with their having been caused for the most part in this way. Other injuries probably received at the same time include fractures of the limbs and spine and further damage to the thoracic cage. The injuries received while floating in the sea have already been described.

Mental Hospitals.—The King Edward's Hospital fund for London has issued a report on the 27 mental hospitals, with 46,000 beds, and the 9 mental deficiency hospitals, with 14,000 beds, in the area covered by the fund. The average age of these hospitals is said to be well over 50 years, and most of them date from the time when the mentally ill were looked on primarily as potential dangers to the community. In some hospitals the patients' clothes are still rolled into bundles and tied to their beds at night, since no storage space is provided for them. Overcrowding occurs to a degree unknown in other hospitals because a mental hospital cannot refuse to admit a certified patient even if there is literally no bed and the patient has to lie on a mattress on the floor. The position with regard to nursing staff is equally unsatisfactory. The Nightingale conception of the matron as mistress of the homestead and responsible to the governing body, not only for the nursing care of the patients but also for all domestic matters affecting the well-being of patients and staff, does not appear to have been accepted in the mental hospitals as it has in all other hospitals. A committee appointed to advise the Birmingham Regional Hospital Board on the standards of staffing required in mental hospitals has recommended that the average ratio of total nursing staff to patients should be 1:4. In England and Wales at present the ratio does not reach 1:6 patients. The number of student nurses in all mental and mental deficiency hospitals has fallen by more than 25% since 1948, giving the ratio of one student nurse to 42.5 patients as compared with one to 3.1 patients in general hospitals.

It is estimated that about $1,540,000 would be needed merely to put in modern catering facilities in the mental hospitals in the fund's area. It is further estimated that to bring the standard of the diet in these hospitals up to that of the regular diet in general hospitals, an increased expenditure of 70 cents per head per week would be required. The King Edward's Hospital Fund for London, which was founded over 50 years ago for the benefit of the voluntary hospitals of London, is aware of the needs of the mental patients in the area which it serves. In the last six years, grants of about $378,000 have been made. The council of the fund, however, has decided to make an allocation to the mental and mental deficiency hospitals of not less than $700,000, spread over three years. Of this sum, it is proposed to earmark $280,000 for three major schemes. The first of these is the establishment of an occupational center at one hospital, which will provide much more than occupational therapy in the restricted sense in which the term is usually understood. Its aim is not only to treat the patient at the more acute stage of his illness but also to prepare him thoroughly for his return to the community; the second is the establishment of a social center at Warlingham Park Hospital; and the third is the establishment of a community center and day hospital in connection with the psychiatric outpatient department of a general hospital on the outskirts of London. The aim of this venture is, so far as possible, to retain the mentally disturbed patient out of a hospital and in his own community.

Employment of Epileptics.—The total number of epileptics on the register of disabled persons is 16,267, or nearly 2% of the total register, according to Sir Godfrey Ince, permanent secretary, Ministry of Labor and National Service, in a speech at the annual meeting of the British Epilepsy Association. This is an increase of 1,189 in the last five years. Of the total on the register, 1,670 are unemployed, a decrease of 103 in five years. The disappointingly small decrease is due in part to the fact that most of the new registrants were unemployed. On the other hand the number of severely disabled unemployed, that is, those requiring sheltered employment, has decreased by 43. This is attributed, in part at least, to the work that has been done in providing sheltered employment by Remploy Ltd., the organization that is providing work in special factories for the severely disabled. Over 400 epileptics are employed by the company, and this represents 7% of their total of severely disabled employees. They find that epileptics on the whole make satisfactory employees. In addition, about 300 epileptics enter the Ministry of Labor's industrial rehabilitation units every year. In these units they spend an average of eight weeks on a course that is aimed at giving them a general toning up, while assessment of their capabilities for employment is made. Of the 300, about 50 leave without completing the course, mainly on health grounds, and of the remaining 250, over 80% are placed in employment or training. In a recent survey of the progress of 7,000 disabled men and women leaving these units, it was shown that, as against an average of 80% for all disabilities, only 56% of epileptics reported satisfactory resettlement six months after they had entered employment. It is the universal experience in the industrial rehabilitation units that, handled with understanding, the epileptic readily settles down to work and can acquit himself as well as the best. Once he realizes that a seizure is not going to cause consternation to anyone, a steady improvement sets in, and the frequency and duration of the seizures diminish. With many, the seizures disappear entirely.

Midwife in the Maternity Service.—In the revised version of its "Memorandum of Policy," published by the Royal College of Midwives, the view is expressed that the routine antenatal care of the expectant mother should be recognized as the duty of the midwife in association with the physician who is responsible for general medical care and attendance. Many physicians are now undertaking antenatal care in their own offices, but this does not absolve the domiciliary midwife from taking her full share of responsibility during the antenatal period. In hospital practice, where obstetricians attend every antenatal clinic, it is considered essential that there be antenatal sessions conducted by midwives. Classes for the mothers in antenatal clinics should be organized by the midwife in cooperation with other members of the health team. The midwife herself should give the teaching on the physiology of labor and the preparations for it, the use of inhalational analgesics, the preparations for the baby, and breast feeding. Provided that she has had the appropriate experience, the midwife may and often does give instruction on relaxation and antenatal exercises to small groups of mothers. Assessment of the suitability of the home conditions for confinement should be made by the midwife in consultation, where necessary, with the patient's family physician. Every mother should be under the constant care of a midwife during the whole course of her labor. Although a physician may be present for part of the time, the midwife should continue to take full responsibility for most normal deliveries. As she can administer inhalational analgesics and, under the Dangerous Drugs Act, can give certain pain-relieving drugs, it is within her power, and it is her duty, to give the mother adequate relief from pain during labor. During the postnatal period the mother and baby should be looked after by the same team as cared for them during pregnancy and labor. The college deplores the practice of some hospitals of sending the mother and baby home, or to other premises, within a few days of confinement, since this makes it impossible to give continuity of care. The care of mothers and babies should remain the responsibility of midwives for at least 28 days. The college also believes that premature babies should be nursed by midwives.

Drugs for Private Patients.—At the recent annual representative meeting of the British Medical Association a motion that private patients have an equal right to free medicine was unanimously carried. This is one of the most keenly debated questions at present. Most physicians are in favor of it, but the Minister of Health has consistently refused to approve this measure. Hitherto, one of his arguments has been that such a concession could not be made without controls equivalent to those accepted by physicians under the National Health Service and that he had been advised that private physicians were not prepared to accept such controls. This last statement is denied by the profession. In the discussion it was reported that the Bristol Local Medical Committee had sent out a questionnaire on this point to 253 practitioners in the area. Of 240 replies, only 3 expressed unwillingness to accept such conditions. One speaker pointed out that it was far from true that the private patients were the wealthier members of the community. Some of the wealthiest patients use the service, while some of the most impecunious have elected to remain private patients. Private patients are classified as those who (1) were too old for insurance contributions in 1948 and who, as a class, are dying out; (2) preferred on principle to pay for their physician's services; and (3) were accustomed to consulting their physicians in private and who believed that it would be unfair to call on a state-employed physician to attend them in this way. If all the remaining private patients decided to put themselves on the lists of National Health Service physicians and were accepted, the government would have to pay a capitation fee for each one of them and provide all the drugs needed. The refusal of the government to accede to the request for free drugs was described as stupid and unjust. Strong exception was also taken to the statement of the committee presided over by Sir Henry Cohen, a former president of the association, that the granting of this concession to private patients would introduce a double standard of practice into private practice. What evidence, it was asked, was there that general practitioners were less considerate of their National Health Service patients than of their private patients?

Commonwealth Tuberculosis Conference.—One of the highlights of the fourth Commonwealth Health and Tuberculosis Conference, organized by the National Association for the Prevention of Tuberculosis and held in London in June, was the presentation of the Sir Robert Philip medal to Dr. P. V. Benjamin, technical adviser on tuberculosis to the government of India, and president-elect of the International Union Against Tuberculosis. The presentation was made by the Duchess of Kent. This is the first award of the medal, which is being given in honor of Sir Robert Philip, the founder of the first tuberculosis dispensary. One of the papers read at the meeting reported the preliminary findings of a combination of thiosemicarbazone and isoniazid. It is claimed that in the experimental animal the new drug is active against the tubercle bacillus, is nontoxic, and so far has produced no drug-resistant organisms. The results of a small clinical trial were encouraging enough to justify a more extensive trial. In another paper Dr. R. G. Cochrane deprecated some of the more optimistic claims being made for chemotherapy and BCG vaccination in the control of leprosy. He noted that relapses were being reported 15 years after sulfones had produced "clinical cures."

Question of Medical Etiquette.—During the recent railway strike a part-time consultant to the board of governors of the United Birmingham Hospitals sent the following letter to one of the strikers: "I am afraid that my principles prevent me from seeing patients on strike except in cases of emergency. Do you mind postponing the visit with your wife? If you will phone for an appointment when the strike is over I will try to fix a convenient date." The striker's member of Parliament, a member of the socialist opposition, raised the matter in the House of Commons and asked the Minister of Health whether the attitude of the physician was not completely unethical and whether this was not political discrimination. In reply the Minister of Health said that if there was any question of a breach of contract within the service, then, that was a matter for which he was answerable and which he would be glad to answer. The question of medical etiquette was not for him to decide nor was the matter of the private arrangements a physician might wish to make with his private patients.

Model Child Welfare Center.—On May 26, the Province of Natal Center of the London University Institute of Child Health was opened. The cost of the center was met by a gift of $336,000 from the people of Natal. This sum represents the balance of the "Salute to Britain Fund," which Natal collected as a gesture of sympathy for Britain during World War II. The center, which is adjacent to the Hospital for Sick Children on Great Ormond Street, is intended as a model welfare center and includes provision for child guidance, consultant and minor ailment clinics for school children, and dental clinics. It will be used by the London County Council as one of its maternity and child welfare centers. A house committee, with representatives of the London County Council, the two borough councils from which most of the children will be drawn, and the Institute of Child Health, will control general policy. The London County Council has undertaken to defray 90% of the cost of maintenance and all the salaries of the medical and nursing staff.

De-Ists.—In an editorial note in *Transactions of the Royal Society of Tropical Medicine* (49:288, 1955), Sir William MacArthur explains that the terms "delouse" and "deflea" are banned in this publication because they are unnatural monsters with Latin heads and English bodies and because native words for these operations—namely "louse" and "flea"—have been used in classical English for centuries and have the advantage of being shorter than their unscholarly substitutes. He concludes his note thus: "Rooms are dusted; gardens, weeded; plants, snailed; trees, barked; grain, husked; elbows, skinned; teeth, scaled; nuts, shelled; potatoes, peeled; gooseberries, topped and tailed; fish and houses, gutted; dogs, wormed; and a poor bird, victim of a half-missed shot, may be feathered." The superfluous Latin "de" would be no more out of place in these English words than it is in those others specifically mentioned. There is no need for the de-ists to out-Latin the Latinists—the verb *pediculare* (not de-pediculare) meant: to free from pediculi.

Perambulating Patient.—In his annual report for 1954-1955, the chairman of the Chester Executive Council reports that for the first time since the inauguration of the National Health Service, the Allocation Committee had to be called. A patient had applied for inclusion in the list of a physician who was not prepared to take him. It was reported that in the last three years this person had been included on nearly every physician's list (about 44) in Chester and that the few remaining physicians in Chester who had not given him treatment were not prepared to accept him as a patient. The Allocation Committee is set up under a scheme that provides that where a patient is unable to secure acceptance by a physician, the committee can assign him to the list of a practitioner of their choice. Fortunately, one of the medical members of the committee was willing to undertake the medical care of this person, but, within a few days of his being assigned to this physician's list, the committee was notified that the patient had moved to another area.

Cause of Itching.—An annotation in the *British Medical Journal* for June 11, 1955, says that, since it was found that a substance indistinguishable from histamine existed in a combined form in human skin, that histamine was liberated when the skin was damaged, and that histamine pricked into the skin caused itching, the view has been widely held that itching of the skin is due to the release of histamine. The view gained support from the observation that antihistamines relieved the itch of urticaria. Two years ago Broadbent published an account of work with cowhage (Mucuna pruriens), sometimes sold as itching powder, and believed at that time to cause itching mechanically. He concluded, however, that cowhage caused a liberation of histamine in the skin, as nettle stings have been shown to do, although it did not contain histamine. He based his conclusion on the observations that extracts of cowhage produced a triple response (like histamine) when injected intradermally, that when cowhage was first extracted the material left behind caused little itching, and that an antihistamine substance given orally reduced the itching caused by cowhage. Subsequently, Bowden and his co-workers showed that a crude extract of the trichomes of cowhage contains 5-hydroxytryptamine. They believe that this substance probably accounts for the pain that occurs when cowhage is applied to the skin, although they could not say whether it was responsible for the itching. More recently Arthur and Shelley claimed that the active principle in cowhage that causes itching is an enzyme called mucunain, and they have described the results of testing a series of enzymes for their power to produce itching. They used the trichomes of cowhage to introduce these enzymes into the skin, after first destroying the mucunain by autoclaving at 250 C for 30 minutes. They then soaked the trichomes in the enzyme solutions, which ranged in strength from 10% downwards. They found that when they introduced a single impregnated trichome into the skin, using a watchmaker's forceps and working under a microscope, a localized itch resulted that was "mild to intense." They tried a wide variety of enzymes finding that only proteinases were active, and of these only the endopeptidases, with activities in the physiological *p*H range. Thus, among the active ones were papain, trypsin, and chymotrypsin, while pepsin and many others were inactive. The three active enzymes were studied as crystalline preparations. They caused itching, with the shortest latent period five seconds and the longest duration 30 minutes. Arthur and Shelley believe that these enzymes cause itching by liberating another substance, but they believe that this is not histamine. Their reason for this is that the active endopeptidases invariably elicited the pure sensation of intense itching without any wheal or flare, whereas histamine and the potent histamine liberator 48/80 never produced itching in the absence of a wheal.

Retrolental Fibroplasia.—A report from the Ministry of Health (*Brit. M. J.* **2**:83, 1955) based on a series of 6,926 infants whose birth weight was not more than 2,000 gm. and who had survived at least two months indicates that 127 of these infants, or 1.8%, had retrolental fibroplasia. There was a marked fall in incidence with increasing birth weight: from 15.3% in infants whose birth weight was under 1,000 gm. to 0.2% in infants with a birth weight between 1,750 and 2,000 gm. All of the infants with retrolental fibroplasia were born in a hospital or were transferred to a hospital within two months. Another report from the Medical Research Council appears in the same issue and is based on a series of 1,095 infants with a birth weight of 1,800 gm. or less, surviving for at least two months and admitted to 17 premature baby units. Of these, 84, or 7.7%, showed evidence of retinopathy; in 39 of these there was a subsequent return to normal fundi. There were 115 babies whose mothers had a history of bleeding during pregnancy, and in this group 17 babies, or 14.8%, were affected with retinopathy. In the 976 whose mothers had no bleeding during pregnancy, there were 67 babies, or 6.9%, with a retinopathy. This difference is statistically significant. Boys were more often affected than girls; the main reason for this appeared to be that they are more immature than girls for a given birth weight. Of the 344 babies who were not given oxygen (mainly the heavier babies), none developed a retinopathy. Of the 581 babies who were given oxygen for less than five days, only 2 were affected (one permanently). There was a steeply rising incidence with increasing length of oxygen administration.

Hospital Survey in Scotland.—The latest survey of regional hospital services published by the Nuffield Foundation concerns the county and city of Perth, which, excluding mental hospitals, controls 1,385 beds, or 10.2 beds per 1,000 population. This is one of the largest groups in Scotland, both in terms of beds and number of hospitals, controlled by one board of management. It provides a wide variety of hospital beds for general practitioners and specialists and is self-supporting, except for facilities for highly specialized branches such as thoracic surgery and neurosurgery, which are organized on a regional and national basis. Of the 1,385 hospital beds in the group, 221 are beds used by patients of general practitioners: 15 beds are for obstetric cases, 108 beds are for general cases, and 98 beds are for geriatric cases. The unclassified beds used by general practitioners are maintained in six cottage hospitals in smaller centers of population.

Euthanasia Again.—Earlier this year the chairman of the South Warwickshire Mental Health Committee, in testifying before the Royal Commission on the law relating to mental illness and mental deficiency, advocated euthanasia in certain cases of gross mental deficiency in children. This evoked a controversy, but, when he spoke on the same subject at the first convention of the National Society for Mentally Handicapped Children recently, his plea was received with applause. Many of the 10,000 members of the society are parents of such children. The chairman believes that there should be a euthanasia panel to which parents of mentally defective children could turn for expert advice on the subject and that the panel, in conjunction with the request of the parents—not the panel alone or the parents alone—should take appropriate action after a decision had been made. He further believes the people of this country do not want to inflict cruelty on anybody; they want to help.

Postgraduate Jubilee.—Hammersmith Hospital, the home of the Postgraduate Medical School of London, is celebrating its 50th anniversary and has been honored by a visit from the Queen. The hospital, at the time it was built, represented a great advance over the Poor Law hospitals and institutions—so much so that the press dubbed it the "paupers paradise." In spite of severe bomb damage the hospital kept going throughout World War II, and in 1945 it underwent great expansion. The number of students enrolled in 1945-1946 was 913, but, by 1953-1954, the number had settled to a more satisfactory level—480. These students are all undergoing residency training or are specialists attending refresher courses. In addition to its other activities, the hospital now houses the Medical Research Council's Radiotherapeutic Research Unit, which includes an 8 million volt linear accelerator and a 45 in. medical cyclotron.

Crash Helmets.—The British Medical Association rejected a motion that the wearing of crash helmets by motorcyclists be made compulsory. Motorcyclists are the major contributors to road accidents, and head injuries account for more than 90% of road fatalities. The act relating to industrial injuries includes a clause exempting miners' and quarrymen's crash helmets from purchase tax but, for some unknown reason, the Treasury has not included helmets for motorcyclists in this category. In 1952, only 2% of motorcyclists wore protective helmets, compared with 30% in 1955. In the 15 months ending March, 1955, of all motorcyclists involved in accidents in London, 18.28% wore crash helmets and in northeastern Scotland 5.17%.

Sterilizing the Intestine.—In the *British Medical Journal* of May 28, 1955, B. J. Fowler reports three deaths following almost complete preoperative sterilization of the feces with antibiotics. Micrococci (staphylococci) are often the only or the predominant organisms subsequently isolated after such a sterilization, and these micrococci are found to be resistant to the drug that has been used in preoperative medication. Although oxytetracycline has often been singled out as the cause of postoperative enterocolitis, this syndrome is no respecter of antibiotics, and Fowler's cases show that the combination of penicillin and streptomycin can be just as dangerous. Fowler believes that the use of intestinal sterilization has gone too far, and he recommends the use of the poorly absorbed sulfonamides. The part played by the Micrococcus in the syndrome is still uncertain. The Micrococcus is not always the cause, and bacteriological investigations are often not done or are done too late. It is likely, however, that where the Micrococcus fills the "bacteriological vacuum" produced by overefficient sterilization of the intestine, the strain that multiplies in the intestine is one that is already drug-resistant when it has reached the victim's alimentary tract. Some lives have been saved by the prompt administration of erythromycin, often the only drug to which these micrococci will respond, but in many patients both specific and general methods of treatment fail, since the condition is acute and fulminating. The liberal use of vitamins may help to prevent this condition, since vitamin deficiency may play a part in its development; however, convincing evidence of this is lacking, and for the present it seems wiser to rely on smaller doses of antibiotics or to return to the use of sulfonamides and energetic measures to eliminate micrococcic infection from surgical wards.

Business Session of British Medical Association.—Physicians attending the annual meeting of the British Medical Association in London passed a motion urging that National Health Service checks be paid monthly rather than quarterly because their own creditors demanded monthly payments. In Newcastle there had been a monthly payment scheme for two years, and the participants were well satisfied. For an individual physician to have to apply for monthly payment was like an admission of hardship before his own colleagues. Dr. A. Talbot Rogers, chairman of the General Medical Services Committee, reminded the meeting that monthly payments would add to the administrative work, the number of employees, and the cost of the service and that any physician could say he wished to be paid monthly without proving hardship.

Family physicians who complained of exclusion from hospital work since the National Health Service started were supported by a hospital consultant, Mr. A. Dickson Wright, who said: "General practitioners who are keen to work in hospitals should have no barriers put in their way. I hate to see this carving up of the profession into two parts by Ministerial edicts."

The meeting decided to press for immediate payment of the compensation promised by the government when the right to sell and buy good will in practices was abolished. The original amount was 185 million dollars; 62 million dollars has already been paid out to retiring physicians and dependents of those who have died. Dr. A. McGlashan, Manchester, pointed out that if he had been able to invest $280 of his compensation in shares, it would now have been worth from $910 to $1,036. Instead, the value of money had dropped and, when paid, the $280 would be worth much less than when the compensation was fixed in 1948.

Mental Defectives.—The Royal Commission on the Law Relating to Mental Illness and Mental Deficiency, sitting in London, heard evidence by the Medical Practitioners' Union, which includes about 4,000 general practitioners, to the effect that instruction of the medical student in the problem of mental deficiency was inadequate. The union said that more time should be devoted in the undergraduate curriculum to practical instruction and field visits. Evidence already presented to the commission by the Ministry of Health and Board of Control, showed that in 1952 the number of mental defectives under care inside and outside of institutions was only 141,607. This figure represents a minority of the mental defectives in Great Britain. One estimate put the total number of mental defectives at 500,000. It follows that over 350,000 are not under official care. Further research and more accurate and comprehensive surveys are needed. The memorandum also stated that it is extremely difficult to institutionalize a mental defective without certification. Many parents object to certification because of the associated life-long stigma. They undertake the care of the child themselves, but complications often arise, especially with boys in early adolescence. Without adequate training the defective then becomes much less manageable. Friction frequently arises between husband and wife, accentuating domestic difficulties. At that stage parents often demand that the child be admitted to an institution. Much trouble can be avoided if treatment in an institution is for the most part voluntary and if there are sufficient places available for admission at an early age.

Boarding Out Older People.—Over three years ago the Exeter Council of Social Service introduced a scheme for boarding out older people. A report on the working of the scheme states that 55 older persons have been boarded out. Of these, 8 have died; 6 have been transferred to welfare homes or hospitals; in 16 the results have been unsuccessful; and 25 have been successfully boarded. So far as practicable, the offers of people willing to accept such boarders into their homes have been carefully checked before recommending an applicant to that home. The final arrangement, though facilitated by the Council of Social Service, has always been between the person and the family with which he is to reside. The offers from prospective adopters in response to newspaper advertisements far exceeds the number of older persons.

Doctor's Mail.—The advertising methods of the pharmaceutical industry has caused irritation and inconvenience to many physicians, most of whom throw postal advertisements into the wastebasket. The advertisements in medical journals provide most of the necessary information and, if a physician requires further information, he may telephone or write to the firm concerned. Some physicians also receive many visits from salesmen, resulting in much waste of time. One constructive suggestion, which has been under consideration by the pharmaceutical industry for some time, is that it would be advantageous to have pharmaceutical advertisements issued in a standard form that could be filed for easy reference. The British Medical Association has taken no official action in this matter.

Ambulance Radiotelephony.—Radiotelephony is being used increasingly by local authorities throughout the country in the control of their ambulance fleets. As there are few points more than 2 miles from an ambulance station in London, the method is not likely to effect much economy. On the other hand, in wartime, civil defense plans would be almost dependent on radiotelephony. As an experiment, therefore, the health committee proposes to equip six ambulances and a staff car for two-way radio transmission, to adapt three more ambulances as reserves, and to establish a control set at headquarters, which would be connected by land lines with a main transmitter on the outskirts of the county.

Royal Society of Medicine.—On June 7 at a banquet to celebrate the 150th anniversary of the founding of the Royal Society of Medicine, the Duke of Edinburgh was admitted as an honorary fellow of the society. In proposing the health of the society the Duke stated his belief that the whole essence of medicine lay in the personal relationship between physician and patient. He was prepared to put up with all the disadvantages and perils of the age—strikes and the threat of the hydrogen bomb—if he could be looked after by "the kind and brilliant men" around him.

Medical Honors.—The members of the medical profession whose names appear in the Queen's Birthday Honors List are: Geoffrey Keynes, consulting surgeon, St. Bartholomew's Hospital, who received a knighthood; Dr. A. R. S. Vickers, the Australian "flying" doctor, who was made a Companion of the Order of St. Michael and St. George; and Dr. Roger Bannister, the Olympic mile runner, who was made a Companion of the Order of the British Empire for services to amateur athletics.

FRANCE

Psychogenic Origin of Psoriasis.—At a meeting of the Society of Paris Hospitals in March, Bolgert and Soulé reported that 50% of their series of 200 patients with psoriasis had such evidence of psychasthenia as anxiety and emotional instability (confirmed by the Rorschach test). They had had depressive crises without obsessional phenomena. In 16% pure agitation without any depressive syndrome was observed; 30% showed no emotional abnormality. In 48% an intimate chronological relation was established between the appearance of the skin lesions and a specific emotional upset. A study of the background in 15 subjects from 3 to 5 years old revealed two patients with obsession and five with anxiety. Familial conflicts such as serious misunderstanding between the patients' parents always acted as the precipitating causes. In the 84 patients in whom heredity factors could be determined, the basis in 37 proved hereditary. The authors believe that a specific neurocrine secretion acts as a link between psychological trauma and the cutaneous lesion. Certain persons appear to be more prone than others to produce such substances. The authors have observed that a pregnancy that is desired can cure a psoriasis that would otherwise have grown worse. Small doses of such sedatives as atropine and eserine benefit some patients. The best results, however, are obtained with psychotherapy and by obtaining the understanding cooperation of the person responsible for the conflictual situation.

Death of Dr. Leclerc.—Dr. Henri Leclerc, the phytotherapist, died at the age of 85 years. He wrote the "Precis of Phytotherapy" and was the creator and the director of the *Review of Phytotherapy.*

SWEDEN

Treatment of Acute Alcoholism.—Dr. Gustaf Myhrman in *Svenska Läkartidningen* for June 10 advocates admitting persons suffering from acute alcoholism to the medical side of a general hospital on the same footing as persons suffering from any other acute ailment. He treated about 100 such patients in this way in 1944. To qualify for this treatment, the mental state of these patients had to be such that they could share treatment with other patients. This meant the exclusion of noisy and violent alcoholics. This disqualification was remarkably rare, and the most common type of patient was characterized by depression, restlessness, and insomnia. Such patients were treated during the first few days by rest, suitable sedatives, and hypnotics. Preparation of vitamin B were also given, and as a rule the patients improved quickly. After a few days they were encouraged to discuss their problems and to regard alcoholism as a disease rather than as a blameworthy character defect. Disulfiram treatment was started, and its mode of action was explained, facilities being provided for a practical demonstration with alcohol tests devised to convince the patient himself of the reactions provoked. As a rule, these patients could be discharged after about eight days. Myhrman states that the more he has practiced this mode of treatment, the more he has been encouraged to follow it. At first he had found his hospital staff inclined to regard alcoholics only as fitting subjects for police attention and institutes specially devised for them, but this negative attitude soon gave place to keen appreciation of the merits of his policy and wholehearted cooperation from all his subordinates. In his opinion alcoholism has become so widespread in Sweden and of such great social importance that it ranks with tuberculosis, cancer, and rheumatism as a national scourge.

Alcohol Consumption.—G. Nelker in *Svenska Läkartidningen* for June 24 reports on the consumption of alcohol in a representative sample of the population of Sweden. About 60% of the persons between the ages of 19 and 26 years in this survey were personally interviewed. About 2,000 heavy drinkers of the same age were also interviewed, and the Swedish Gallup Institute undertook the interviewing of about 5,000 persons of all ages with regard to their drinking habits. About 7% of the men between the ages of 20 and 25 and 9% of those over this age had a record of contravention of the alcohol laws in the preceding 10 years. This means that about 195,000 men over the age of 15 fell foul of the law, in most cases on account of drunkenness. This was classified as gross in 47,000 men and as less serious in the rest. As there were only about 4,000 women in the same category, there was only one woman convicted of the abuse of alcohol to every 50 men. This striking sex difference is characteristic of a spirits-drinking country, as distinguished from wine and beer-drinking countries in which women are more noticeably affected. About 80% of the men consumed alcohol to a moderate or very slight extent. The rest could be almost equally divided between heavy drinkers and teetotalers. For women it could be said that a third consumed spirits regularly, another third did so occasionally, and the remaining third were teetotalers. The author concludes that the liquor problem is more serious for the youth of today than it was for earlier generations.

Recession of Tuberculosis.—Dr. Enar Brandel, in *Svenska Läkartidningen* for July 1, notes that Norrbotten County in the north of Sweden has had such a bad name in the past with regard to tuberculosis that its dramatic decline since 1944 is the more cheering. In 1944 there were 242 deaths from tuberculosis, or 107 per 100,000 inhabitants; in 1954 there were only 41 such deaths, or 16 per 100,000. Deaths from tuberculosis in patients under the age of 30 fell from 130 in 1944 to 5 in 1954. In 1954 there was only one death from tuberculosis in childhood, while the corresponding figure for 1944 was 14. There has also been a marked fall in the number of patients registered by the Central Tuberculosis Dispensary as suffering from tuberculosis, the numbers for the two years in question being 6,476 and 3,637 respectively. The credit for the improvement must be given to a combination of mass radiography, BCG vaccination, antibiotic and chemotherapeutic remedies, the progress of chest surgery, the raised standard of living, and increased natural resistance to tuberculosis as demonstrated by the more chronic course it now runs.

Rickets.—In *Nordisk medicin* for June 2, Dr. Jan Winberg reports a survey of most of the children's hospitals in Sweden with regard to the number of patients with active rickets treated by them during the period 1944 to 1953. The diagnosis in most of the 2,530 cases thus collected was confirmed by roentgenograms and chemical analyses of the blood. In 1944, 1.55% of the children treated in the hospital suffered from rickets, whereas in 1953 the corresponding figure was down to 0.55. The credit for this improvement must be given to a falling birth rate, to more intensive supervision of children at welfare centers, and to stricter diagnostic criteria. About 65% of these patients were boys. In only 15 patients was the rickets refractory to vitamin D, and in less than 10 patients were clinical signs of vitamin D poisoning observed. In none of these cases did this poisoning have any permanent ill-effects.

SWITZERLAND

Meeting of the International College of Surgeons.—The meeting of the International College of Surgeons in Geneva in May marked the 20th anniversary of the founding of the College in Geneva by Dr. Max Thorek of Chicago. Besides its strictly scientific activities, the college has concerned itself with mutual aid between surgeons. After the terrible bombing that destroyed a part of London, the college helped to rebuild the Royal College of Surgeons. During the floods that devastated the Netherlands, the college aided the surgeons whose offices had been damaged with repairs and new instruments. The college has 12,000 members from 64 countries. A volume of 1,200 pages, with more than 600 illustrations, is available to those who wish to read the papers presented at the meeting. Among the speakers was Prof. G. Domagk of Wuppertal, a winner of the Nobel prize in medicine, who helped to develop the sulfonamides. Switzerland honored Dr. Max Thorek by presenting him with a work of art that will go to the International College of Surgeons Hall of Fame in Chicago.

Meningoencephalitis.—In the *Bulletin of the World Health Organization* (vol. 12, no. 4), it was stated that meningoencephalitis, a virus disease whose importance has only recently been recognized, may be difficult to distinguish from poliomyelitis on either clinical or pathological grounds so that in such cases the correct diagnosis can be made only in the virus laboratory. The clinical, epidemiological, pathogenic, and immunologic aspects were studied by specialists from Slovenia, Austria, and the Netherlands, and the serologic aspects were studied by Pond and Russ of the Army Medical Service Graduate School, Washington, D. C. The increasing importance of virus diseases is considered to be due to the reduced danger from bacterial diseases resulting from effective control, improved diagnostic methods and, for some virus diseases, from a true increase in incidence. The principal vector of meningoencephalitis is a tick, which has been observed in rural and wooded areas and chiefly affects people between 10 and 30 years of age. About 95% of all cases occur from May to September. The course of the disease is generally diphasic; a prodromal stage being observed about 10 days after a person has been bitten. It is influenza-like, but vomiting and a slight stiffness in the neck may also occur. This stage may last from 2 to 5 days, being followed, after a quiescent period of about 10 days, by the meningoencephalitic stage, with high fever, violent headaches, vomiting, loss of consciousness, delirium, and coma. Leukopenia is found in the prodromal stage, and neutrophilic leukocytosis in the meningoencephalitic stage. Another characteristic feature is a progressive increase of protein in the spinal fluid. There is a wide diversity of clinical phenomena in different patients. Even the differentiation from tuberculous meningitis is frequently difficult. An organism was isolated from the blood; the antigen prepared from the brains of mice infected with this organism fixes complement with serums from typical cases of the disease. This organism appears to be a neurotropic virus and to be the causative agent of the disease in Slovenia.

In Austria the epidemiological features were similar, but only one-third of the patients reported tick bites and many others reported only mosquito bites. The incubation period is variable. Abortive cases were observed. Among the 304 patients hospitalized at the Neurological Clinic, Graz, 175 cases were of aparalytic meningeal form, 50 were preparalytic, 27 were spinal paralytic, 20 were bulbospinal or ascending paralytic, 7 were bulbar paralytic, 3 were radiculitic or transmyelitic, and 22 were encephalitic. The case fatality rate was 4.6%. The clinical course was usually diphasic, as in Slovenia, and the changes in the spinal fluid showed a close similarity to those seen in poliomyelitis, but paralysis of the shoulder girdle and upper arm predominated. The postmortem examination showed the findings of acute encephalitis, with changes most marked in the gray matter. Histological findings revealed extensive involvement of the anterior horns of the spinal cord, medulla oblongata, pons, and especially the Purkinje cells of the cerebellum. The possibility of louping-ill virus, Russian spring-summer encephalitis, Czech tick encephalitis, and poliomyelitis must be considered. Differential diagnosis from poliomyelitis rests on serologic and immunologic bases, as clinical and postmortem findings alone are not sufficient. Treatment is symptomatic and supporting.

The pathogenic and immunologic properties of the virus have been investigated by a group in Leyden, Netherlands. Two virus strains were isolated from the central nervous system of two fatal human cases in Austria. Monkeys, mice, and chick embryos proved susceptible. The experimental disease in monkeys was characterized by acute meningoencephalomyelitis, localized particularly in the gray matter of the brain stem, cerebellum, medulla, and anterior horns of the spinal cord. The virus produced discrete lesions on the chorioallantoic membrane of the chick embryo. In monkeys viremia was demonstrated for at least six days before the development of the clinical illness. The virus was shown to be closely related to that of Russian spring-summer encephalitis. Neutralizing and complement-fixing antibodies could be demonstrated in patients' serums. In a further study, also carried out in Leyden, attempts to transmit the disease by the bites of mosquitos engorged on infected animals proved unsuccessful. Pond and Russ studied the reactions of two viruses isolated during the 1953 epidemics in Slovenia and Austria in neutralization tests. They were found to be indistinguishable under the conditions of test from the agents called Russian spring-summer encephalitis virus, Czech encephalitis virus, or louping-ill virus, which are believed at present to be strains of the same agent.

Influenza Epidemic.—According to reports made available to the World Health Organization, the influenza epidemic of the winter 1954-1955 was mild and caused relatively few deaths. It was similar to previous epidemics that seem to have followed each other at intervals of two or three years ever since the epidemic of 1918. Virus B was identified in every outbreak that occurred last winter. Although it is too soon to present a complete picture, some idea of the nature and extent of the last epidemic can be obtained from the following descriptions of outbreaks in various countries.

The first epidemics in the Northern Hemisphere were reported in Wales and the northeast of England in October. In January the incidence increased among adults. The infection spread to most parts of the country and receded in February. Virus B was largely responsible, but a few cases of influenza A were diagnosed in South Wales, the Midlands, and London. Toward the middle of December several cases were reported in Slovenia, but it was not until January that outbreaks were noted in other parts of Yugoslavia. In the last week of February the incidence increased Zagreb, and in the first week of March it also rose in Serbia, particularly in Belgrade. At the beginning of January, Canada reported the beginning of an epidemic involving several hundred cases in the area around Calgary, Alberta. In the last week of the month, the disease abated in this sector, but an outbreak was noted in Ontario. At the beginning of January there was an outbreak in northern Holland. By the middle of February influenza had spread throughout the rest of the country, especially among children. There were a few deaths attributed to secondary micrococcic pneumonia. In the second half of January there was an increase of nasopharyngitis in West Germany, especially in the Bremen-Hamburg-Lübeck area and mainly among children and young adults. The infection remained mild until the beginning of February. An epidemic also developed in Hesse. The infection was very contagious and affected 30% to 40% of the schoolchildren in town and more than 50% in rural areas. At the end of January, nearly 10% of the adults were also affected. In the first week of February, the epidemic spread to the Rhine area, the region of the Main, Schleswig-Holstein, and Bavaria, where the main focus seemed to be located. In the second half of February, the infection receded in the north, after having affected nearly 15% of the population. During these epidemics the presence of virus B was demonstrated, but virus A was identified in certain cases in the central and northern parts of the country.

In Helsinki, Finland, a focus of influenza appeared in the second half of January, mainly affecting children. In the same period a relatively mild epidemic of influenza was reported in Japan among children of primary schools in Honshu. At the beginning of February, the disease spread to the primary schools of Tokyo and to several other prefectures of Honshu. In the United States, absence among the schoolchildren of Portland and Multnomah County, Oregon, increased from the beginning of February because of an unusual prevalence of respiratory infections. Reports received in mid-February indicated a large number of cases of influenza-like infections in Syracuse, N. Y., and in Maine. In Austria, reports of cases of influenza increased rapidly beginning in the first week in February and began to fall off in the second week of March in most of the country, with the exception of the northeast. In the first week of February, influenza morbidity increased in Norway, Sweden, and Switzerland. These outbreaks reached their maximum during the week ending March 19.

Russia Returns to World Health Organization.—The Soviet Union withdrew from the World Health Organization and became an inactive member about six years ago, as did the other iron curtain countries. On July 8 it was announced in Geneva by a representative of Russia that his government now proposes to take an active part in the work of the World Health Organization, to take up membership in the International Bureau of Education, and to contribute 2 million rubles to the United Nations Children's Fund in the form of services and equipment for maternity and child care.

CORRESPONDENCE

CORTISONE TREATMENT FOR SARCOIDOSIS

To the Editor:—With regard to the article by Israel, Sones, and Harrell in the Oct. 2, 1954, issue of THE JOURNAL, page 461, entitled "Cortisone Treatment of Sarcoidosis," we agree with most of the statements made by the authors but take exception to two of their major points. We have never claimed, as suggested in the article, that the sarcoid process itself becomes aggravated or spreads because of cortisone. Our experience, like theirs, is that there is either clearing or no change at all in the pulmonary lesions during and immediately after treatment (*Am. J. Med.* 15:468, 1953. Ibid. 15:477, 1953). We have not used the term "rebound relapse," and this term has no meaning for us. We have described patients in whom the pulmonary parenchymal infiltration reappeared after clearing with cortisone. This we regard simply as continued activity of the disease process that had been temporarily halted by treatment. We are aware that retreatment will often bring about complete clearing again. The truly untoward effects of therapy described by us are not commented on at all by the authors, and it would appear that a detailed functional study of these patients during and periodically after completion of cortisone therapy was not made. This refers to the occasional worsening of lung function in the form of impairment of diffusing capacity and/or the development of emphysema. It might be added in passing that follow-up studies of these patients to date confirms the presence of these abnormal findings. It is admittedly impossible to state that these changes would not have occurred without cortisone therapy, but the rapidity of their development suggests that there is a cause and effect relationship.

The second point is the development of tuberculosis following cortisone therapy for sarcoidosis. The statement made by the authors that "clearly these cases represented instances of tuberculosis simulating sarcoidosis" cannot be supported. This criticism conceivably could be leveled at our patient in case 5 in whom diffuse pulmonary disease and various other systemic manifestations were present at the start of treatment, but we believe that the large number of bacteriological studies as well as the negative tuberculin tests made this possibility unlikely. In our patients in cases 6 and 7 the evidence of sarcoidosis was unequivocal. After the development of positive cultures for Mycobacterium tuberculosis, the patient in case 6 became bacteriologically negative after chemotherapy was begun and had a long course of chemotherapy. He has continued to be tuberculin positive and has had progressive pulmonary involvement, which we attribute to sarcoidosis, since no bacteriological evidence of tuberculosis appeared up to one year after cessation of antituberculous therapy despite progressive roentgenographic worsening. Our patient in case 7, after the development of positive cultures, was not treated with antituberculous chemotherapy, but, after serial positive cultures for two months (organisms proved virulent for guinea pigs), his gastric washings became negative and have remained so to date. In this patient also, bilateral parenchymal infiltration subsequently appeared, associated with negative tuberculin tests as well as negative cultures—clearly evidence of exacerbation of the sarcoid process without progression of his tuberculosis.

In all three of these patients, because of the rapid development of tuberculosis, we have little doubt that a tuberculous infection had been present previously and that this was brought to clinical attention as a result of cortisone therapy. We do not contend that an entirely new infection occurred and progressed to clinical tuberculosis within as little as one month's time. Our patient in case 8 is in a class by himself, and it is difficult to state precisely what the cortisone therapy accomplished. Evidence of tuberculosis was present prior to cortisone therapy, and we do not contend that cortisone caused it. This case merely emphasizes the clinical difficulty of evaluating the condition of these patients if intensive bacteriological studies are not done. It serves no purpose to say, in retrospect, that patients with clinically typical sarcoidosis actually had tuberculosis simulating sarcoidosis when all the usual criteria for the diagnosis of sarcoidosis have been fulfilled. Even if it be granted that in some patients the syndrome of sarcoidosis may be caused by the tubercle bacillus, the point is that it is often impossible to recognize these cases clinically until cortisone therapy changes the findings into those of frank tuberculosis. All the evidence available in such patients prior to treatment is strongly against the diagnosis of tuberculosis. It would seem, therefore, that in a certain number of cases that look like sarcoidosis evidence of tuberculosis must be expected to develop with cortisone therapy, and we do not have any really effective way of deciding beforehand which cases fall into this group.

F. J. LOVELOCK, M.D.
D. J. STONE, M.D.
Veterans Administration Hospital
408 First Ave.
New York 10.

This letter was submitted to Drs. Israel, Sones, and Harrell, who have replied as follows:

To the Editor:—Drs. Lovelock and Stone appear to differ with us significantly only in their beliefs that (1) a large proportion of patients with sarcoidosis have tubercle bacilli lurking in their tissues and (2) that it is frequently impossible to distinguish tuberculosis and sarcoidosis. The difficulty in distinguishing between sarcoidosis and tuberculosis is well recognized. It should be recalled that at one time sarcoidosis was generally regarded as an atypical form of tuberculosis. At present there is almost unanimous agreement that sarcoidosis is nontuberculous in etiology. The rarity with which tubercle bacilli have been found in sarcoidosis (Rostenberg, 1953) has been one of the most persuasive reasons for this conclusion. The fact that most investigators have rarely encountered tuberculosis following corticotropin and cortisone treatment of sarcoidosis (Shulman and others, 1952; Siltzbach and Ehrich, 1954; Carstensen, 1954) has provided additional evidence that in most instances the two diseases can be differentiated.

The unusual experience of Drs. Lovelock and Stone with untreated as well as treated patients may be attributable to their reliance on the Kveim test. They state that in most of their cases "the diagnosis was proven histologically by tissue biopsy or Kveim reaction." The Kveim reaction is not sufficiently well standardized to permit its use as a substitute for biopsy study. We have found the Kveim test frequently positive in tuberculous subjects. Demonstration of epithelioid tubercles does not "prove" the diagnosis of sarcoidosis, for a similar appearance may be observed in tuberculosis, histoplasmosis, and beryllosis. A biopsy is essential to the diagnosis of sarcoidosis, because, in addition to demonstrating compatible tissue changes, it permits bacteriological, mycological, and chemical study of the excised material. If these criteria for the diagnosis of sarcoidosis are strictly adhered to, tuberculosis should rarely supervene. We agree that the indiscriminate use of cortisone in patients with unsubstantiated diagnoses or with minor manifestations is to be deplored. Fear of tuberculosis should not deter the physician from administering this agent in well-studied cases of sarcoidosis, especially those in which there is ocular, myocardial, or progressive pulmonary involvement, where its clinical value seems indisputable.

ANTIBIOTICS

To the Editor:—In the May 21, 1955, issue of THE JOURNAL, an editorial by Dr. Maxwell Finland on antibiotic-resistant micrococcic infections excellently summarizes the problem. From my short experience in the private practice of pediatrics, I find that it is probably even more a problem outside than inside the hospital because of the inclination to treat infections without sensitivity tests on the organisms. In the vein of Dr. Bean's "Omphalosophy: An Inquiry into the Inner and Outer Significance of the Belly-Button," reviewed with tongue-in-cheek in THE JOURNAL, June 18, 1955, page 616, I have summarized my own feelings.

With penicillin, sulfas, and the "mycins" as our aid,
We've "polished off" all kinds of germs for more than one decade.
To give a drug without a test we thought was rather "foxy"
As every time we knocked them out: Bacilli and the cocci.

And every time there came a germ that showed us some resistance
They found another "mycin" drug to come to our assistance.
But now we've no new "wonder drugs" to add to our collection,
And here we stand, disarmed against the dreaded staph. infection.

Physicians (and the public, too!), a trifle too vainglorious,
Are now quite shocked to find that they can't "shake off" H. Staph. Aureus.
Too tough for all our armaments, they sit around and mock us,
Those indolent and purulent obnoxious clumps of coccus.

Although we talk of "Atom" bombs, I'll worry when they're falling;
Infection with resistant germs to me is more appalling.
And if they do not shortly find some new and potent drugs,
The world won't go to dogs at all, but right back to the "bugs!"

CHLOROPHYLL DEODORIZATION

To the Editor:—In the April 9, 1955, issue of THE JOURNAL, page 1279, "Chlorophyll Solution in Deodorization of Advanced Carcinoma of Head and Neck," deserves special comment. The survey emanates from a cancer research center of good repute. The findings, I am sure, are accurate and sincere. It is unfortunate that the findings and conclusions are based on a liquid solution applied in the oral cavity. At best, this type of therapy would be unsatisfactory in such an area. The wasted material and its intimate contact with salivary secretion would nullify its efficacy. In other locations of the body, were the same preparation applied, it could have been controlled far more accurately. This would also hold for the application of chlorophyll ointment. These statements are borne out by the findings of the Therapeutic Trials Committee of the American Medical Association (*J. A. M. A.* **140**:1336 [Aug. 27] 1949). The results have been corroborated by many independent workers. My personal experience with chlorophyll was limited principally to the use of chlorophyll tablets given internally. The product used was Chloresium. I have described the results elsewhere (*West. J. Surg.* 60:363 [July] 1952). Since that time, I have taken a special interest in this preparation. The results have been satisfactory for body odors, foul-smelling wounds, infected sinuses, colostomies, and other malodorous conditions. In fairness to the authors, might I suggest the use of the chlorophyll tablet internally to reduce the malodor produced by the condition generally. As for the local lesions, it would be impossible to eliminate the odor from morbid or necrotic tissue by any means, least of all with a solution that simply bathes the surface. Here I believe the best therapy would be actual surgical excision or medicinal agents now available on the market for the elimination of this necrotic material.

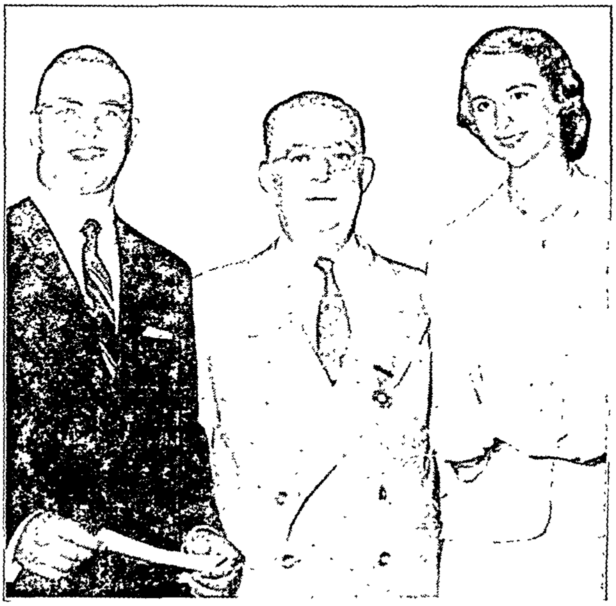
ELKS SCHOLARSHIPS

To the Editor:—The Elks National Foundation, of which I am a trustee, is a large trust fund held in perpetuity with no overhead expense. The entire expense is paid by the Grand Lodge, and all income is used for humanitarian purposes. Over the years we have given many college scholarships, and at the last meeting in Philadelphia the Elks National Foundation gave 56 college scholarships. The winner of the first place in the girl's division was Kathleen Joanne Kampmann, Naches, Wash. The top award in the young men's department went to Robert Allen Evans, El Dorado, Kan. Robert will enter Yale University New Haven, Conn., as a premedical student next fall. Kathleen is a premedical student at the University of Washington, Seattle. I am happy that the two top winners this year are prospective doctors. In addition to many contributions and its humanitarian activities, the Elks National Foundation has become interested in cerebral palsy, and I presume that 300 or 400 scholarships in cerebral palsy have been granted by this foundation in the last two or three years. I am not interested in advertising the Elks, but I am interested in the voluntary way of doing things. Several of our most valuable students are now doctors of medicine. This year's top winners received high grades in competition with hundreds of others, and I believe that both of them had grades in the neighborhood of 99%. They were chosen from nearly 5,000 youngsters from every state and territory of the United States. The applications are judged on a basis of 60% for scholarship and 40% for character and citizenship in school and community.



Top students receive Elks National Foundation scholarships. *Left to right:* Robert Allen Evans, El Dorado, Kan.; Dr. McCormick; and Kathleen Joanne Kampmann, Naches, Wash.

BOOKS FOR KOREA

To the Editor:—I read with interest the letter in the July 16, 1955, issue of THE JOURNAL from our chairman, Dr. Howard A. Rusk, on "Books for Korea." Due to the excellent cooperation of the physicians, hospitals, medical schools, and medical societies of the United States, this has been an extremely successful and important venture. I regret that the address to which future contributions of books should be shipped was incorrect. It should read: Medical Section, Sharpe General Depot, Tracy Annex, Lathrop, Calif. Shipments should be marked "KORMEDED."

THE LEISURE CORNER

PICNICKERY—A SCIENCE

With warm weather upon us, the thoughts of many doctors the country over tend to wander off in the general direction of the great outdoors. To some, warm days bring to mind a favorite mountain trout stream and the monster that got away. To others, they are a reminder of thrilling tennis games won—and lost. But to many more, the warm weather brings thoughts of carefree hours spent in the country doing nothing or, more precisely, picnicking.

Actually, picnicking is not just doing nothing. Not too long ago, it took the foresight and forethought of a master strategist to plan a really successful picnic. Today, thanks to a number of modern gadgets and conveniences, this is no longer so. Picnicking has been transformed from a highly difficult maneuver into what has been called "the simple science of picnickery." Webster's dictionary has this to say in the way of a definition for the word picnic: "A pleasure party, the food for which is usually provided by members of the group and is eaten in the open air."

Because people enjoy picnics in different ways, a more precise definition would be misleading. To some, an enjoyable picnic requires little more than those two basic ingredients, food and fresh air. To others, such an outing may appear dull and incomplete unless combined with other pastimes, ranging from competitive games to boating at a nearby lake. A master at picnickery—a word, incidentally, that lexicographers have grossly overlooked—fashions an outing to fit everyone's taste.

If there are children in the group, one should make a point of bringing along a rubber ball, preferably one of rather light weight and not overly small in size. With the aid of this simple toy and a little imagination, one can devise any number of exciting games for the youngsters. An example is modified baseball, where the fist serves as a bat. The chance of injury to any of the participants in such games is practically nil. The less agile members of the party, meanwhile, could be playing cards—a particularly versatile picnic pastime. Other sedentary games that have proved popular at picnics include scrabble, charades, and word games. Fishing, generally speaking, makes a poor time-filler at picnics—primarily because it so often takes up too much time. A few nibbles on one's line can make a picnicker forget all about food and his companions and stay glued to one spot grimly determined to "get that fish." So, unless one is planning to fish primarily and picnic secondarily, rod and reel should be left at home beyond temptation's reach.

Picnic sites are many and varied. Careful planning can make an outing in one's back yard a delightful experience. The usual picnic site, however, is a spot far removed from home—the sea shore, perhaps, or a park. Probably the greatest convenience of the present-day picnicker is his automobile. It makes sure he gets there, providing, of course, he in turn has made certain it was in good working order before starting out. After one gets there, however, he may soon be wishing for the peace and convenience of the city unless he is aware of a few basic facts and has bothered to invest in a few rather essential items. In the basic facts department is the business of selecting a good picnic site. To start with, one should never pick a spot because it is beautiful and has a grand view and forget about everything else. Low-lying, damp areas, for instance, should be avoided no matter how pleasant they may appear. For, with the coming of evening, such spots are frequently invaded by armies of mosquitoes and other insects that waste little time making a picnic out of picnickers. While on the subject of insects, it should be remembered that ants, too, enjoy picnics. So, before settling down, one should make sure the spot is nowhere near an ant colony.

Even a doctor may forget to bring a first-aid kit, which, needless to say, could be a big mistake. For cuts, bruises, and insect bites are frequent occurrences on such outings, particularly if there are children in the party. Children, naturally, have the grandest time of all. To make sure that they play safely, one should see if there are any bodies of water, deep holes, or similar hazards in the vicinity. Also, children should be taught as soon as possible to recognize dangerous weeds such as poison oak and ivy.

Next, and usually the key to a picnic's success or failure, is the matter of food. While this is normally thought to be totally in the women's department, assistance of an indirect nature would be both fruitful and welcome. This contribution should not come in the form of cooking tips shouted from the living room to the kitchen but in the form of a few reliable implements bought especially for this picnic and picnics to come. These implements are designed to keep cold foods and drinks cold, warm ones warm, and get uncooked food cooked.

Nothing is as tasteless, for instance, as a potato salad or a bottle of soda that has been in the sun without adequate protection. To guard against this picnic hazard there are portable insulated picnic containers. In selecting one, special attention should be given to weight. Every extra ounce feels more like a ton after a long hike, so that containers made of heavy metal would add needless strain to an outing. Lightness plus smart design—an important feature from the wife's standpoint—are incorporated in some picnic containers. The Skotch Kooler, for instance, is an insulated container in smart plaid that has a four gallon capacity and can keep foods and drinks hot or cold for many hours.

Incidentally, the problems entailed by using ice—its weight, bulk, and general sloppiness—can be avoided by utilizing a newly developed dry cold refrigerant that comes in cans. The cans contain a chemical substance that freezes quickly when placed in the refrigerator's freezing compartment. A six ounce can has the cooling equivalent of nine ice cubes and can be used over and over. It should be remembered that insulated picnic containers are also useful as a means of keeping foods warm. If that is the purpose, one can make doubly sure that a casserole dish, for instance, stays warm by heating a brick in the oven, wrapping it in tinfoil, and placing it underneath the dish. A cool drink of the homemade variety is always welcome at a picnic. To make sure it stays chilled, there are insulated jugs of considerable capacity.

If a cookout is planned, no special equipment other than wood or charcoal may be necessary. Many state parks and recreation areas have grills for the use of picnickers; however, many areas do not. The safest thing to do, unless one knows for certain whether such facilities exist, is to bring along a portable charcoal grill. A word of caution to those doctors who remember the open campfires used in their camping days—many states expressly prohibit starting open fires for cooking or other purposes, except in certain designated areas. Other states require a special permit. So, no matter how good a woodsman one is, a charcoal grill could come in handy.

Some of the newer grills make starting a fire a foolproof operation by incorporating a cleverly engineered draft system. This insures against another picnic dampener; for many a temper has been lost and a box of matches used up in fruitless attempts to get a fire started. Failure in this department could be due to lack of dry kindling or the fact that too much wood or coal has been dumped on the kindling at one time. An added bit of insurance here would be to take along a can of flammable liquid specially prepared for such contingencies. This last mistake, smothering a fire with too much fuel, is one that amateur chefs never cease to make. With the average grill, for instance, about 12 briquettes should be placed on paper, not more. Once the fire is well started, another six balls should be added. This is enough to cook for a dozen people, so that continuing to add coal would be both a waste and a mistake. After the dinner is cooked and done comes the important job of putting out the fire. Countless forest fires have been started by campers who carelessly left a few not totally extinguished coals behind.

Many, many more facts could be noted about this science called picnickery. Most are common sense rules, others of the kind that one never really learns without practice. Fortunately, the mistakes that are usually made by beginners are of the type that leave no scars. And mistakes or none, few pastimes bring more pleasure to more people. Perhaps all that really needs to be learned about picnickery has been summed up by the Boy Scout organization in two simple words: "Be Prepared."

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Experience with Phenylindanedione in the Management of Acute Myocardial Infarction. G. M. Breneman and E. M. Priest. Am. Heart J. 50:129-135 (July) 1955 [St. Louis].

The authors list the properties desired in an ideal anticoagulant drug and report that Soulier and Gueguen in France have used 2-phenyl-1,3-indanedione as an anticoagulant since 1947. The drug has a coumarin-like action but is not a coumarin derivative. It is reported to have rapid onset of action, wide range of therapeutic safety, and few toxic reactions. This drug has been used at the Henry Ford Hospital as the routine oral anticoagulant since June, 1953. The authors report their experience in 251 consecutive cases of proved myocardial infarction to whom the drug had been administered for a minimum of 48 hours. These cases were unselected except that those patients in whom any type of oral anticoagulant was contraindicated and all those receiving the drug for less than 48 hours were excluded. The initial dose was 300 to 500 mg. given in divided doses in the first 24 hours. Subsequent dosage usually varied from 100 to 200 mg. daily, also given in divided doses. An occasional patient required smaller or larger daily amounts to maintain the desired hypoprothrombinemia. The over-all recovery rate was 90%. Thromboembolic complications occurred in 3.5%, and hemorrhagic complications in 1.6% of the patients. Two skin eruptions were observed that required the immediate discontinuation of the drug therapy. A number of favorable reports have appeared about this drug, and the authors feel that their experience confirms its value in the management of acute myocardial infarction. They regard it as the best currently available oral anticoagulant.

Pharmacological Combination of Corticotropin, Ascorbic Acid, and Adenosine Triphosphoric Acid in Crises of Bronchial Asthma. L. Rosa and G. Bergami. Minerva med. 46:936-941 (April 7) 1955 (In Italian) [Turin, Italy].

Actavis, a combination of 4 I. U. of corticotropin (ACTH), 20 mg. of adenosine triphosphoric acid (ATP), and 1 gm. of ascorbic acid, was given to 20 patients several days after they were admitted to the medical clinic of the University of Bologna with severe status asthmaticus. The drug was given slowly by intravenous injection. The initial dose of one-half vial on the first day was increased to one to three vials daily and then tapered off when improvement was observed. Tolerance to the drug was good except in two patients in whom a burning sensation, nausea, dizziness, and headache necessitated discontinuance of the therapy. Excellent or good results were obtained in 16 patients in whom the status asthmaticus was interrupted. The condition remained unchanged in the other four patients, despite the fact that they received three vials of the preparation daily. Thirty days after completion of the treatment, a relapse was observed in four patients, in one of whom it was severe. These encouraging results indicate a probable synergy between the various components of Actavis.

Thrombosis of the Abdominal Aorta: A New Physical Sign. G. W. Covey. Nebraska M. J. 40:205-210 (June) 1955 [Lincoln, Neb.].

Many of the recent reports dealing with occlusive disease of the abdominal aorta stress the so-called insidious, slowly progressive, chronic thrombosis involving the aortoiliac segment in contrast to acute thrombosis or to embolic occlusion of the aorta and other arteries in this region. The histories of four men, ranging in age from 47 to 60 years, show that one had a more acute type and three had typical insidious chronic thrombosis. Intermittent claudication is the cardinal symptom. When the terminal aorta and iliac arteries are involved, this symptom is not, however, the intermittent limp due to pain in the calf of the leg or foot. It is an aching sensation just short of pain and related in quality to the sensation of fatigue. Moreover, it is typically located in the region of the hips and low back, and has been referred to as the "hip-type" of claudication. Gangrene rarely occurs in cases with chronic insidious occlusion, as contrasted with the acute, sudden vascular closure in which it is common. In three of the cases a loud systolic murmur was heard over the aorta, above the umbilicus, and over one or both the common iliac arteries. Such a murmur occurs in other conditions, especially in aneurysm of the abdominal aorta, but there is an uncommon element in this particular murmur; it may be heard over the spinous processes of the lumbar vertebrae. Here it is even louder and more musical in character than it is over the anterior aspect of the abdomen. It is loudest over the vertebrae when the patient lies in a prone position. This murmur was first heard by the author in the third case and also in the fourth case. He watched for this murmur in many other conditions, but failed to find it. He feels that it may prove a useful sign in the differential diagnosis of chronic, insidious occlusion of the terminal aorta, or in occlusion of the iliac vessels. It probably occurs only when the aorta itself is involved in the thrombotic process or when both common iliac arteries are occluded. Although Leriche stated that loss of penile erection is one of the two cardinal symptoms, none of the patients presented here complained of impotence, and of the two questioned about this symptom neither admitted it. Only one of the three patients having chronic, insidious thrombosis was subjected to aortography. This procedure served only to confirm the clinical diagnosis. The clinical diagnoses were made on the basis of the "hip-type" of claudication combined with the absence of vascular pulsations. The peculiar musical murmur over the lumbar spine is the new sign. Since this report was written, four additional patients have been observed in whom occlusion of one or the other common iliac artery was present. One of the four had impotentia erigendi. None exhibited the lumbar musical systolic murmur. This tends to confirm the theory that involvement of both iliac arteries or of the terminal aorta is needed to engender this murmur. A long and active life is the probable outlook for many patients who have the chronic, insidious type of aortoiliac thrombosis. Occlusion of the renal arteries by cephalad extension is the greatest danger. Medical management has been used in the three cases of chronic insidious thrombosis herein reported. Two patients believe they can walk farther before developing pain after Priscoline or other similar drugs have been taken for several months. Accurate evaluation of drug therapy, however, is difficult. Surgical therapy varies. Lumbar sympathectomy, unilateral or bilateral, has been used alone or combined with ligation and removal of the thrombosed segments of the various arteries. Thromboendartectomy has been performed, at times combined with a support made from fascia lata to reinforce the weakened arterial wall. The latest procedure, and perhaps the most logical, is excision of the involved artery and replacement by an arterial graft.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Rehabilitation of the Patient with Chronic Rheumatoid Arthritis: Two-Year Study. E. W. Lohman. J. Chronic Dis. 1:628-637 (June) 1955 [St. Louis].

Rheumatoid arthritis is a progressively crippling disease of unknown origin for which there is no known cure. The fact that severe crippling and invalidism ultimately appear in from 10 to 15% of the patients with this condition makes the problem of their rehabilitation socially and economically important. Rehabilitation was formerly considered applicable chiefly to patients with a "burned-out" disease process. The advent of the adrenal and pituitary hormones for the better control of the inflammatory process of rheumatoid arthritis, however, suggested the possibility that a combined medical and rehabilitation program might be used to advantage in patients with active disease. The favorable impressions obtained from work with a pilot group of severely crippled patients who were hospitalized and treated with a combination of cortisone and rehabilitation measures led to the establishment of a full-scale research project in December, 1951, at the Goldwater Memorial Hospital. The various types of special treatment needed included physical therapy, occupational therapy, remedial exercises, psychotherapy, psychological testing, vocational counseling, and assistance from social workers. Patients admitted during the first year of the study (group 1) had to meet the following criteria: 1. They had to be within the 21 to 55 year age group, with severe functional impairment but without any obvious need for corrective orthopedic procedures. 2. The rheumatoid process had to be active and progressive. 3. There could be no medical contraindications for hormone therapy. Less rigid criteria were adopted in the second year in order to obtain a group for comparison with the first, but the group 2 patients still had to have active and progressive rheumatoid arthritis, to be free from problems requiring primarily orthopedic correction, and to be incapacitated for gainful employment. Patients in group 1 had an average age of 46 years, with a disease duration of 13 years. Those in group 2 averaged 40 years in age and had a disease duration of 7 years. All were evaluated medically, functionally, and psychosocially before treatment was begun. Cortisone or hydrocortisone in oral doses was the drug used in most cases. Physical rehabilitation measures were started as soon as the maintenance dosages of the drug were established, and the patients were then continued on both drug and rehabilitation measures. They were scored on their proficiency in the activities of daily living before treatment began, after the establishment of maintenance drug therapy, and repeatedly thereafter. Evaluation of the results at the end of the first two year period showed that 14 of the 18 patients in group 1 and all 20 of those in group 2 had been discharged from the hospital. Only four group 1 patients still required custodial hospital care and even in these there had been a 20% increase in function. Functional improvement in the other group 1 patients ranged from 26% to 39% in the case of those who were totally self-sufficient on discharge. One of the totally self-sufficient group 1 patients was placed in a job. Full-time jobs were also found for 7 of the group 2 patients, 15 of whom were totally self-sufficient. Several of the patients not placed in jobs are now working at home. These results show that patients with rheumatoid arthritis can often be saved from invalidism by a broad program of rehabilitation.

Chemotherapy of Tsutsugamushi-Disease. S. Katsura. Acta med. et biol. 2:725-753 (Dec.) 1954 (In English) [Niigata, Japan].

The rickettsiosis known as tsutsugamushi disease was formerly treated by symptomatic measures, but the introduction of *p*-aminobenzoic acid, of chloramphenicol and of various antibiotics has decidedly changed the therapy of this disease. The author and a number of other Japanese investigators have demonstrated that tsutsugamushi disease can be cured by these drugs. In four patients treated with *p*-aminobenzoic acid medication was started between the second and eighth days of illness. Fever began to subside from three to five days after onset of treatment and disappeared in from seven to eight days; treatment was continued for about two days after subsidence of fever. No relapse occurred in these patients. Of 31 patients with tsutsugamushi disease, 7 were treated with chloramphenicol, 16 with chlortetracycline, and 8 with oxytetracycline. During treatment with these drugs the elevated temperature subsided as a rule within two and a half days. Although these drugs were effective in smaller doses and in a much shorter time, relapses occurred in a number of patients. The author also studied the in vitro rickettsicidal action of chlortetracycline, oxytetracycline, chloramphenicol, erythromycin, magnamycin, *p*-aminobenzoic acid, and several other drugs. In addition, he studied the effects of these drugs in mice that had been inoculated with Rickettsia tsutsugamushi. Factors influencing cure and relapse of tsutsugamushi disease were likewise investigated. The author feels that these and other studies have clarified to some extent the mode of action of the aforementioned drugs in tsutsugamushi disease. Many investigators have recognized that in rickettsial diseases these drugs, particularly the antibiotics, do not destroy the Rickettsia but inhibit growth. In his studies on tsutsugamushi disease the author confirmed that in addition to the direct inhibitory effect on R. tsutsugamushi, an activating influence is exerted, which gives vitality to the cells of the body and enables them to counteract the effects of the rickettsias. He also found that if antibiotics are to be used from the onset of the disease, it is not advisable to give them in such large doses as to rapidly counteract the increase in temperature; on the contrary, it is better, both for formation of immunity and consequently prevention of relapse and for economy of materials, to reduce fever slowly by administering small doses over a longer period.

Infectious Mononucleosis: Statistical Study of 77 Cases. R. Savosnick. Tidsskr. norske lægefor. 75:311-312 (May 1) 1955 (In Norwegian) [Oslo, Norway].

A seeming definite increase in the frequency of infectious mononucleosis during recent years is ascribed in part to greater attention to the general character of the disease and more frequent systematic examination of the blood, leading to correct diagnosis. In the five year period ending in 1952, 77 patients with infectious mononucleosis (44 males and 33 females) were treated in the epidemic department of Central Hospital in Trondheim. The disease rarely occurs in persons over age 30; most of the patients were between 16 and 20. Two-fifths of the patients were admitted with a diagnosis of diphtheria, one-fourth with a diagnosis of angina, and only one-tenth with the right diagnosis. While hepatic affection is believed to be present in most cases of infectious mononucleosis, liver damage is seldom so grave that the patient becomes icteric. There was visible jaundice in only two of these cases. The dominating introductory symptoms are sore throat, fever, and "influenza symptoms." In over half the cases more than 70% mononuclear cells were found, but it is the pathological lymphocytes that are pathognomonic for infectious mononucleosis and on which the diagnosis is based. Paul-Bunnel's reaction was positive in 19 out of 29 cases. Eighteen of the patients were treated with sulfonamides, 19 with penicillin, and the last 40 with Aureomycin. In all three groups the average duration of illness was between 10 and 13 days.

Treatment of Severe Hypertension with Methonium Compounds. V. Rønnov-Jessen. Ugesk. læger 117:549-558 (May 5) 1955 (In Danish) [Copenhagen, Denmark].

Methonium compounds were administered to 96 patients with severe hypertension and severe hypertensive disturbances. Nine patients died during the treatment, seven after treatment ended, from cerebral hemorrhage, heart failure, cardiac infarct, or renal insufficiency. The contraindications were uremia, recent cerebral or cardiac thrombosis, or psychic reduction that prevented the necessary cooperation. In judging the effect, the 84 patients treated for from 5 to 49 months were considered. In 16 cases the treatment was supplemented with reserpine. In each case treated the purpose was to find the dosage suitable to produce the greatest reduction of blood pressure and subjective disturbances with so few side-effects that there would be no temptation to give up the treatment. In many cases the patients became practically free from symptoms, and the majority improved subjectively. There were also objective improvements in a number of cases. Evaluation of the prognosis was not possible. In some cases the treatment prolonged life. The ideal hypertensive agent combines strong uniform effect with easy administration and few side-effects. Reserpine now most nearly meets the requirements, but the hypertensive action is often moderate and, particularly in severe hypertension, considerably weaker than that of the ganglion-blocking agents. These should at present be reserved for severe cases of hypertension that cannot be satisfactorily treated with reserpine. Severe hypertension with acute encephalopathy, symptoms of heart failure, or rapidly deteriorating renal function should be treated primarily with ganglion-blocking substances. Careful instruction of the patients is necessary for reasonable safety in the application of these drugs.

Combination Treatment of Hypertension with Pentapyrrolidin and Reserpine. I. Persson. Ugesk. læger **117:**568-571 (May 5) 1955 (In Danish) [Copenhagen, Denmark].

Because of the severity of the hypertension in 16 cases investigated, a powerfully active hypotensive substance had to be applied at the start of treatment. After pentapyrrolidin treatment was given for up to 10 months in eight of the cases and after pentapyrrolidin was given in as large doses as possible for two weeks in the remaining eight cases, 0.1 mg. of reserpine three times daily was administered in all cases and the dosage was slowly increased to 0.25 mg. twice daily, with simultaneous reduction of the pentapyrrolidin dosage. On the combination treatment of reserpine and pentapyrrolidin the subjective symptoms disappeared and the blood pressure dropped considerably, in most cases to normal values. The reserpine allowed reduction of the pentapyrrolidin dosage, and the possibility of side-effects, especially constipation, was lessened. There are practically no contraindications for reserpine, and the contraindications for the combined treatment are those for pentapyrrolidin. Caution is urged in cases with marked reduction of renal function. Recent thrombotic processes in brain and heart are considered contraindications. Coarctation of aorta, aortic insufficiency, pheochromocytoma, glaucoma, organic pyloric stenosis, and tendency to ileus contraindicate the combination treatment. The results of long-term treatment with these substances are not yet known.

Treatment of Hypertension with Reserpine (Serpasil): Preliminary Report. T. Hilden, A. R. Krogsgaard and E. Godtfredsen. Ugesk. læger **117:**572-575 (May 5) 1955 (In Danish) [Copenhagen, Denmark].

In 6 out of 38 cases of essential hypertension, treatment with reserpine could not be completed because of side-effects or lack of effect and cooperation. Satisfactory results were achieved in 16 cases after an average of six months' treatment. In the remaining 16 cases reserpine treatment was supplemented with hydralyzine (Apresoline). The reserpine dosage was individualized. Except in some cases, where up to 3 mg. daily was given for a short time, the highest daily dosage was 2 mg. On continued treatment the dosage was from 0.5 to 1.5 mg. daily, apportioned in four doses. The mean blood pressure fell an average of 27 mm. Hg. In five cases retinal changes regressed, and in two cases the electrocardiographic changes improved. In most cases improvement occurred in the subjective symptoms. Side-effects were generally slight. In some cases depression was seen, which in two cases necessitated termination of the treatment in spite of otherwise favorable results. On the basis of their results together with reports from the literature the authors conclude that reserpine can give satisfactory results, first and foremost in milder cases of hypertension. In other cases, especially more severe ones, the effect will often prove inadequate; here, combinations of reserpine with other hypotensive agents can be important.

Fatal Hexamethonium Intoxication. V. Rønnov-Jessen. Ugesk. læger **117:**584-587 (May 5) 1955 (In Danish) [Copenhagen, Denmark].

The case reported illustrates the possible danger connected with peroral hexamethonium treatment. In a woman, aged 68, with arterial hypertension, symptoms of shock with paralytic ileus and considerable uremia set in after five days' treatment with 250 mg. hexamethonium bromide five times daily. Death ensued in spite of fluid therapy, blood transfusion, and administration of nor-epinephrine. Necropsy showed dilatation of stomach and small intestine and localized gangrene in the distal part of ileum and bladder, presumably secondary to thrombus formation in the vessels. The moderate hexamethonium bromide dosage would not in most cases have affected the blood pressure significantly. Patients with severe hypertension should be hospitalized. Treatment with ganglion-blocking agents should be begun in the hospital to allow close observation of the patient during the introductory phase and timely treatment if needed. If ganglion-blocking substances are to be used in the practice, the introductory dose should never exceed 125 mg. of hexamethonium bromide or 20 mg. of pentapyrrolidin bitartrate, and the dose should be increased slowly. The smallest dose that will give subjective relief must be found. Careful instruction of the patient is the absolute rule.

Mechanism and Pharmacological Blockade of Dumping Syndrome: Preliminary Report. A. Dyk. Wien. med. Wchnschr. **105:**487-489 (June 18) 1955 (In German) [Vienna, Austria].

Dyk's observations on persons who had not undergone gastrectomy and to whom dextrose was administered by the intrajejunal route, in some of them after normal ingestion of food, suggest that the dumping syndrome may be elicited selectively by enteral administration of dextrose. The occurrence of the syndrome seems to depend on a disturbance of absorption, possibly in the sense of phosphorylation or dephosphorylation in the intestine and in the intestinal wall respectively. An elucidation of the actual pathogenesis of the dumping syndrome and a properly directed therapy may be expected from a closer clarification of these disturbances and their relationship to the functional hypophysial-adrenal system and, in a wider sense, to the entire autonomic nervous system. The vegetative mechanism on which the course of the syndrome is based is one of a sympatheticotonic state, which by a dumping process changes into a vagotonic state in a kaleidoscope-like fashion. Blocking of the syndrome can be effected with the aid of phenyl-ethyl-methyl-hydantoin given in doses of 0.1 gm. approximately one hour before the meal, and that probably by producing a primary vagotonic starting position. Thus a simple and reliable drug is available to give symptomatic relief to the patient with the dumping syndrome.

Acute Micrococcic (Staphylococcic) Enterocolitis as a Serious Complication of Antibiotic Therapy. P. Rentchnick. Deutsche med. Wchnschr. **80:**892-895 (June 10) 1955 (In German) [Stuttgart, Germany].

Profuse diarrhea, which occasionally was accompanied by shock or even resulted in death, occurred in some patients who were given antibiotics to achieve sterilization of the colon preparatory to a surgical intervention, or to treat pneumonia or an infection of the urinary tract. Morphological and bacteriological studies revealed that this complication can be traced to an acute micrococcic (staphylococcic) enterocolitis, which is a superinfection leading to intoxication of the organism, particularly the nervous system, with an enterotoxin. About 12 patients with this secondary micrococcic enterocolitis were observed at the Canton Hospital in Geneva during the past year. The disorder usually begins between the third and fifth day after onset of treatment with antibiotics, but sometimes earlier or later. The first symptom is usually a profuse diarrhea, which is accompanied by temperature elevation up to 40 C (104 F). Dehydration and loss of electrolytes rapidly result from the severe diarrhea, and signs of shock such as falling blood pressure, cold extremities, anxiety, oliguria, and retention of urea are evident. Although the clinical picture suggests toxemia or septicemia the blood culture is nearly always negative. It is important to recognize the first signs of this disorder, and in order to do this the intestinal function of patients being treated with antibiotics should be watched carefully. While a mild diarrhea and the fact that the stool loses its odor do not necessarily demand the instantaneous interruption of the antibiotic therapy, the stool should at once be subjected to bacteriological analysis, and if Micrococcus aureus is found in profusion, antibiotic therapy should be stopped and steps should be taken to treat the superinfection, restore the electrolyte balance, and counteract the shock. Erythromycin has proved to be the drug of choice for the treatment of resistant strains of micrococci.

Scleroderma: Clinical and Anatomic Study of 28 Cases. A. González Salvatierra. Rev. méd. Chile **53**:162-180 (March) 1955 (In Spanish) [Santiago, Chile].

Twenty-eight patients with diffuse scleroderma were observed in a hospital of Chile for the last nine years. There were 26 women and 2 men. The disease appeared in most of the patients in their middle age and progressed for several years. Symptoms in order of frequency were Raynaud's syndrome, arthralgia, pigmentation alone or with vitiligo, rigidity and hardness of the skin, and progressive deterioration of the general state of health. Edema, paresthesia, and cardiac insufficiency each were present in a patient. Two or more symptoms appeared simultaneously, in some cases as early as 7 or 20 years prior to the full clinical picture. Visceral involvement occurred before, together with, or after appearance of skin manifestations, without any relation to the acuteness or extension of the skin lesion. It manifested itself suddenly and unexpectedly by the occurrence of insufficiency of the involved organ. The heart, bronchi, lungs, and kidneys were the most frequently involved organs. Other organs and tissues were involved with less frequency but with the same degree of severity. There is no curative therapy for either the skin or the visceral disease, but the visceral lesion is more acute than the skin lesion. The most acute visceral involvement was that of sclerodermal nephropathy. It developed suddenly with hypertension, renal insufficiency, oliguria, progressive uremia, and a rapid acute course with fatal termination about a month after appearance of the hypertension. In the author's cases visceral involvement occurred in 14 patients (50%). Cardiopathy occurred in four patients, bronchopneumonic involvement in four, esophageal scleroderma in four, and nephropathy in two. These cases are reported in detail, with roentgen pictures and microphotographs. Four patients died from bronchopneumonia or from nephropathy. Three autopsies were performed. The pathological examination in bronchopneumonic involvement showed diffuse bronchial and pulmonary fibrosis with infiltration, bronchiectasis, alveolar infiltration, a stage of acute bronchopneumonia, and intense fibrosis of the arteries and arterioles with thickening of the intima. The pathological picture of sclerodermal nephropathy consisted of cortical necrosis with external zones of hemorrhage or infarct, endoarteritis, fibrinoid necrosis of blood vessels, and necrosis of the glomeruli, tubuli, and interstitial tissue. The medulla of the kidney was normal.

The Treatment of Pulmonary Tuberculosis with Iproniazid (1-Isonicotinyl-2-Isopropyl Hydrazine) and Isoniazid (Isonicotinyl Hydrazine). C. M. Ogilvie. Quart. J. Med. **24**:175-189 (April) 1955 [London, England].

After the antituberculous properties of hydrazine derivatives of isonicotinic acid had been reported during the early part of 1952, isoniazid was released for general use and was universally accepted as an effective antituberculous agent. The isopropyl derivative (iproniazid) was made available for clinical trials only in certain centers. The author summarizes the known differences between iproniazid and isoniazid and confirms that higher plasma levels can be obtained with iproniazid in man. Iproniazid proved ineffective against tuberculous infections resistant to isoniazid but effective against sensitive infections. The emergence of resistant strains was noted in a high proportion of patients treated with iproniazid alone. Two comparable groups of patients with pulmonary tuberculosis (mainly recent disease, or a recent spread of chronic disease) were treated for two to four months with iproniazid and isoniazid, respectively, each drug being combined with streptomycin. Average gains of weight and the incidence of toxic effects were considerably greater in the group treated with iproniazid. Progress, as judged by temperature response, the closure of large cavities, and the incidence of bacteriological resistance, was more favorable in the iproniazid group. The higher plasma levels attained in iproniazid therapy may well account for the greater incidence of toxic effects in patients treated with this drug. It seems unlikely, however, that the differences in the isoniazid and iproniazid plasma levels during therapy are sufficient to offset the fact that iproniazid is about 60 times less active than isoniazid against the tubercle bacillus in vitro. Why, then, should patients treated with iproniazid progress at least as well, and also gain considerably more weight, than those treated with isoniazid? The author found that patients with bacteriologically resistant infections gained more weight with iproniazid therapy than they had done with isoniazid therapy when their tubercle bacilli were sensitive. Further trials showed that the gain in weight of tuberculous patients treated with iproniazid cannot be directly correlated with the initial severity or the progress of the disease and that iproniazid therapy can also induce an increase in the weight of certain nontuberculous subjects. Similar results have not been obtained with isoniazid. The author suggests that iproniazid therapy exerts some specific effect upon appetite, and thus upon general nutrition, quite apart from its antituberculous properties and that this factor may have contributed to the relatively favorable progress of the group of patients treated with iproniazid.

Studies on Pulmonary Cancer: 5. Influence of Occupation on Occurrence of Primary Epithelial Pulmonary Tumors. L. Kreyberg. Tidsskr. norske lægefor. **75**:342-344 (May 15) 1955 (In Norwegian) [Oslo, Norway].

The new carcinogenic situation has led to increased incidence, almost exclusively in men, of pulmonary carcinomas due to irritants. The etiological factors must be sought in the milieu of work and/or the habits of life. Two hundred seventy-five cases of primary epithelial tumors of the lung, microscopically examined and typed, are tabulated in three categories according to the kind of tumor and to occupation, i. e., work in open air and housework, office and professional work, and dusty work. The fairly even distribution of group 2 tumors in the different categories supports the earlier conclusion that they occur evenly in the population irrespective of special carcinogenic milieu. The tendency to the development of tumors of the irritation group is greater in men doing dusty work than in men in the other two categories, and there is a definitely increased incidence of group 1 tumors in men engaged in office and professional work. While the results indicate that dusty work is in some degree important for the development of the special pulmonary tumors, the work itself does not afford a full explanation. There is reason to investigate other sides of men's activities, among them their habits of life, to discover, if possible, other essential factors. Theoretically, dusty work in itself need not be significant, if it is accompanied by other factors relevant to the development of pulmonary tumors.

Cleansed Cavities and Bullous Neocavities After Chemotherapy. A. Bernou and J. Brun. Presse méd. **63**:894-896 (June 11) 1955 (In French) [Paris, France].

The bullous images seen at roentgenography to persist or appear after chemotherapy of ulcerocaseous tertiary tuberculosis do not all have the same structure or origin. Those that are sequelant are of two types: finely encircled bullous cavities and sclerocystic cavities with somewhat thickened connective structure. These lesions are penetrable to Lipiodol and may simulate bronchiectasis. There are also bullous neocavities appearing at the time of retraction of the lesion; they may be located at the site of the original cavity or at some distance from it. These cavities may be cystic bronchiectasis with bronchoalveolar dilatation occurring at the time of retraction of the lesion and furthered by the consecutive sclerosis, or, more commonly, single or multiple emphysematous bullae, the pathogenesis of which is not clear. It would seem that retraction of the lesion in chemotherapy causes distention, leading to emphysematous bullae by way of compensation. The bullae appear more frequently in those portions of lung where the elastic tension has been especially dissociated and made fragile by the tuberculous process. Chemotherapy plays a part in this development in that it produces retraction of tuberculous lesions and atrophic interstitial sclerosis. Isoniazid is especially important in the latter phenomenon. A practical conclusion drawn from these considerations is that radical treatment ought not to be practiced on sequelant bronchiectasis or emphysematous bullae in the mistaken belief that they are persisting cavities. Even bullous or sclerocystic cavities are not necessarily best treated by excision, as shown by the fact that, in the authors' follow-up of 18 patients with pseudoemphysematous cavities, no relapses occurred during a period of from two to eight years.

Cortisone and Syphilis: Results of and Comments on Corticotherapy in Ninety Cases of Syphilis. P. de Graciansky and C. Grupper. Semaine hôp. Paris **31**:2141-2161 (June 20) 1955 (In French) [Paris, France].

Ninety patients with syphilis of various clinical forms were given cortisone, hydrocortisone, or corticotropin before a course of penicillin therapy. This procedure was successful in preventing or attenuating Herxheimer's reaction. It also affected the clinical manifestations of the disease. 1. Chancres stopped oozing, became softer, and rapidly epidermized. 2. Certain features of secondary syphilis were favorably influenced, but less so as they were more severe. 3. The gummas and ulcerations of tertiary syphilis were greatly benefited. 4. There was evidence to indicate that corticotherapy had an effect on the functional signs of aortic syphilis. 5. In nervous syphilis, pain resistant to other kinds of therapy yielded to cortisone. Local injections of hydrocortisone proved excellent in the treatment of four patients with tabetic dislocating arthropathy of the knee. 6. Symptomatic benefit was obtained in interstitial keratitis of late congenital syphilis. Corticotherapy had effect also on the laboratory signs of syphilis: Treponema, reagin, amboceptor, and anomalies of the cerebrospinal fluid. The normal course of syphilis after penicillin therapy was unaffected, nor was the sensitivity of Treponema organisms to penicillin altered. In patients allergic to penicillin and in pregnant patients, cortisone favors a better tolerance to the antibiotic. Its value in the severe pain and visceral paroxysms of tabes, in arthropathy, and in interstitial keratitis make cortisone an excellent adjuvant in the treatment of these forms of syphilis. Hydrocortisone appears to be the best agent to administer and is now being used routinely by the authors.

Use of Pentolinium Tartrate With and Without Hydralazine in the Treatment of Severe Hypertension. H. M. Perry Jr. and H. A. Schroeder. New England J. Med. **252**:1057-1066 (June 23) 1955 [Boston].

Pentolinium tartrate is a pentamethonium derivative in which the two terminal quaternary nitrogen atoms are included in a pyrrolidine ring rather than each being trimethylated. This substance is an autonomic blocking agent like its parent methonium compound. It is longer acting and has greater absolute effect on blood pressure, coupled with a relatively smaller effect on gastrointestinal motility, than the hexamethonium ion. Pentolinium tartrate was given orally to 30 severely hypertensive patients; 12 had received no previous effective antihypertensive therapy, 12 had shown low tolerance for hexamethonium chloride in combination with hydralazine, and 6 had manifested late toxic reactions to hydralazine after their blood pressure was well controlled by such combined therapy. The authors describe the dosage employed in each of these groups, cite illustrative case histories, and describe studies on urinary pentolinium recovery. As a chemical sympathectomizing agent, pentolinium tartrate demonstrated a limited but definite improvement over other methonium salts for some, but not for all, patients. By weight it was approximately 5 times as effective in lowering elevated blood pressure as hexamethonium chloride; ion for ion it was 10 times as powerful. Although every unpleasant manifestation of autonomic blockade was observed, there usually was relatively less parasympatholysis and hence fewer and milder untoward reactions. It was most useful in persons with very severe hexamethonium side-effects, particularly those who needed the greatest amounts of that drug for effective control of blood pressure. Unfortunately, the vasomotor instability accompanying normotension in occasional patients requiring large hexamethonium dosages was often more frequent and persistent with pentolinium tartrate. Substituted hydrazines remain unique substances without which it has been impossible to control the most severe stages of hypertension, even with enormous doses of blocking agents. When begun before the appearance of frank uremia, the combination of pentolinium tartrate and hydralazine gave satisfactory control of the worst cases of hypertension. The six patients in whom collagen disease had followed the administration of hydralazine were given pentolinium tartrate combined with other drugs, with varying results.

Occurrence of Gastric Cancer Among Patients with Pernicious Anemia at the Boston City Hospital. N. Zamcheck, E. Grable, A. Ley and L. Norman. New England J. Med. **252**:1103-1110 (June 30) 1955 [Boston].

Diagnostic index files from the general wards of the Boston City Hospital, the Outpatient Department, the Thorndike Memorial Laboratory, and the Mallory Institute of Pathology provided 1,222 names of patients with pernicious anemia diagnosed between 1915 and 1951. Observations were recorded on 658 of these patients by a group of physicians investigating the pathogenesis of pernicious anemia at the Thorndike Memorial Laboratory. Strict criteria were employed for making the diagnosis of pernicious anemia. Of the original 1,222 patients, 7 had diagnoses recorded of both pernicious anemia and gastri cancer. Only 28 of these, however, were sufficiently well documented to be accepted for this study. Twenty-one of these wer among the 658 Thorndike patients. The lesion was seen grossl at autopsy in 14 patients and at laparotomy in 11 others. Th remaining three had unequivocal clinical and x-ray evidence c gastric cancer. These studies confirm previous reports of th high prevalence of gastric cancer among patients with perniciou anemia. Depending on the sample selected, however, the fr quency of gastric cancer in the present series varied from le than 1% to more than 11%. For instance, in the Thorndik group it was 3.2%, and in the Boston City Hospital (without th Thorndike group) it was 1.2%; in 59 autopsies performed i the Thorndike group it was 11.9%, and in 108 autopsies at th Boston City Hospital it was 6.5%. The authors feel that th high rates of cancer in pernicious anemia patients justify th routine use of screening tests. The relative simplicity and a curacy of gastric cytology justify consideration of its use as screening adjunct.

Jaundice Associated with the Administration of Chlorpromazin SKF-2601-A (Thorazine): Report of Three Cases, with Biopsi of the Liver. E. R. Movitt, M. A. Meyer, A. M. Snell and othe Gastroenterology **28**:901-913 (June) 1955 [Baltimore].

The authors report three patients who sustained liver inju during the course of chlorpromazine therapy. Needle biopsi of the liver were obtained from them all; one patient was su jected to an exploratory laparotomy that failed to reveal a evidence of extrahepatic biliary obstruction. All patients r covered. The clinical picture is that of obstructive jaundice, wi elevated serum alkaline phosphatase and total serum choleste but normal flocculation tests. Histological studies reveal intr hepatic cholestasis as the most prominent feature. The autho emphasize that the possibility of chlorpromazine-induced jau dice should be entertained in all icteric patients, particular when they present diagnostic problems involving possible su gical exploration.

Problem of Late Recurrences of Malaria in Man. M. Crey J. Leng-Lévy and G. Laborie. Presse méd. **63**:877-878 (June 1955 (In French) [Paris, France].

The authors report a case of relapse of malaria with Plasm dium malariae in a 56-year-old man a week after he had unde gone an operation on the liver. He had been infected 36 yea previously in the Orient and had not had any symptoms in th intervening period. It is pointed out that, among patients wi late recurrences of malaria, there are a rare few who can tran mit the disease to others via blood transfusions. Others ha febrile bouts of malaria, and, since there is no question reinfestation in nonpaludic countries, this raises the proble of late recurrence after a long period of persistence of th original infestation in some latent form. The possibility malaria must be envisioned so that differential diagnosis can b made between paludic attacks and pseudopaludic attacks in th nonpaludic countries. Evidence from the literature is cited t show that this concept of late recurrences of malaria is consistent with present knowledge on malarial pathology.

SURGERY

Routine Supraclavicular Biopsy in Suspected Bronchiogenic Carcinoma. E. F. Skinner, J. Hall, D. Carr and S. G. Robbins. Am. Surgeon 21:590-600 (June) 1955 [Atlanta, Ga.].

Seventy male and 30 female patients between the ages of 4 and 78 years who were suspected of having bronchogenic carcinoma were subjected to supraclavicular biopsy. The results of biopsy were positive in 43 of the 100 patients. The results of biopsy were negative in 41 patients, and they were negative also in 16 other patients with such diseases as bronchiectasis or pneumonia. Thus the total incidence of negative results from supraclavicular biopsies was 57% and that of positive results 43%. This is believed to be a highly profitable ratio since even biopsy of the lungs is not always completely diagnostic. In 10 patients, the diagnosis was made clinically of bronchogenic carcinoma but was not confirmed by tissue study. None of these patients had positive results from a supraclavicular biopsy. In four instances no tissue was sent to the laboratory for examination as the surgeon did not believe that clinically important nodes were present. This was an error as sometimes small nodes contain microscopic cancer. In all patients subjected to supraclavicular biopsy the prescalene fat pad and the nodes therein should be sent to the laboratory for pathological study and also for bacteriological examination. In 18 patients no nodes were palpable, and yet results from supraclavicular biopsy were positive. In 25 patients the nodes were palpable, and the results of supraclavicular biopsy were positive. In many of the patients, the positive results of the biopsy saved the patient major surgery, as such distant metastases made surgical cure highly improbable. Of the 43 patients in whom the results of biopsy were positive, 41 had no definite diagnosis before the biopsy was done, but they had had many other clinical tests. Thus in 41 of the 100 patients the first positive cellular diagnosis was established by the supraclavicular biopsy. Biopsy of the supraclavicular nodes is helpful often enough to be used frequently or even routinely in all patients in whom bronchogenic carcinoma is suspected before major surgery is done.

Results of Pulmonary Exeresis for Tuberculoma. M. Bérard, P. Galy and E. C. Saubier. Presse méd. 63:893-894 (June 11) 1955 (In French) [Paris, France].

The authors use the term "tuberculoma" to define tuberculous foci that are caseous, altered, stratified, and of a certain volume. Eighty-two such lesions were found among 1,200 operative specimens from lung excisions performed between 1948 and 1954. Results in the 82 patients with tuberculoma were strikingly good; there was no mortality, and only two recurrences (occurring in 2 of the 12 patients with excavated lesions). Most patients returned to their previous occupations after three to six months' rest. Tuberculoma can be said to be a relatively benign form of tuberculosis, in which the lesions have a tendency to localize and organize. Owing to this defense on the part of the body, exeresis is simple and easy. To conclude from this reasoning that excision can be dispensed with altogether would be dangerous, since excavation of the lesions is always a possibility, with the attendant danger of bronchial dissemination. It is pointed out that exeresis is not so good a treatment for caseous foci that do not fulfill the requirements for diagnosis of a tuberculoma (this could only be verified at examination of the operative specimen); in a series of 136 excisions of caseous foci there were 10 recurrences.

Investigations into Thymic Disease and Tumour Formation. G. Keynes. Brit. J. Surg. 42:449-462 (March) 1955 [Bristol, England].

In 1942 Keynes was asked to perform a thymectomy on a woman with a severe, progressive myasthenia gravis. The myasthenia was arrested after the operation and ultimately abolished. Encouraged by this success, he proceeded to extirpate thymus glands from myasthenic patients, and in due course the operation of thymectomy became well established as a recognized form of treatment for myasthenia. This author is chiefly concerned with the thymic tumor, or thymoma, found in patients with myasthenia gravis, and sometimes in patients without symptoms. Of the first 11 patients with tumors operated on between April, 1942, and January, 1948, only 3 survived for more than two years and only one is known to be alive at present. Three of the 11 died postoperatively. This is in striking contrast with the general results of thymectomy when there is no tumor. Among these the postoperative mortality is 4%, and 65% of the survivors are apparently cured or nearly so. It also became plain that tumor formation was to be expected in a considerable proportion of patients with myasthenia gravis. Of 260 patients with myasthenia gravis who came to the author's attention 41 had a thymoma, an incidence of 15.4%. The author analyzes a total of 51 thymic tumors, 10 others having been contributed by four other surgeons. Twenty-two of the patients were men, and 29 were women. There is still much confusion about thymic tumors, because of the large variety of tumors that may arise in the mediastinum, the uncertainty as to which of them have really arisen from the thymus gland, and the difficulty experienced by pathologists in classifying the true thymomas. Pathologists have not made up their minds whether to call the true thymomas innocent or malignant, and the very name of lymphoepithelioma that they have commonly applied to them betrays their uncertainty. The presence of a thymic tumor is nearly always associated with severe symptoms. The response of these patients to neostigmin is slow and sometimes incomplete, so that suspicion should be aroused at an early stage. Whereas myasthenia gravis usually has a rather slow onset, rapid onset is a conspicuous feature of the myasthenia due to a thymoma. Treatment of the tumor by primary operation has proved unsatisfactory. Since 1947 the author has treated every thymic tumor diagnosed before operation by means of the million-volt machine, and a few patients in whom the diagnosis was missed have been treated very soon after operation. At present, 26 patients have been treated in this way, 21 of whom have subsequently had an operation performed. In one the tumor was not removable, and the patient died 18 months later. Of the remaining 20 patients, 4 have died, one was no better, 3 improved at first but relapsed afterwards, 8 have considerably improved, and 4 are quite well and symptomless. This is a very different result from that obtained earlier in the series with primary operation. Great accuracy of exposure to the x-ray beam is desirable to avoid injury to the lungs, so that precise localization of the tumor by preliminary radiology is essential. Tomography may be of great assistance. The total dosage, up to 4,000 r, may have to be spread over a period of four weeks or sometimes longer. During the course of the x-ray treatment the tumor, as demonstrated by radiology, can be seen to shrink and sometimes to become less opaque. While the first five thymic tumors treated by the author were not diagnosed before operation, he learned gradually what to look for in the x-ray film. In commenting on the pathological aspects, he suggests that the term malignant has been too rigidly interpreted, but he gives reasons why all of these tumors are in some respects malignant. Thymic disease and tumor formation is a complex problem.

Arterial Replacement by "Orlon" Cloth: A Preliminary Report of Its Experimental and Clinical Use. J. B. Kinmonth, G. W. Taylor and R. H. Lee. Brit. M. J. 1:1406-1408 (June 11) 1955 [London, England].

Grafts used as substitutes for arteries serve chiefly as scaffolding on which the tissues of the host develop a new vessel. Success does not depend on the survival of cells from the donor. Excellent results have been obtained in cases in which no attempt was made to maintain the viability of the cells of the graft. The use of artificial materials as arterial prostheses seems, therefore, to be logically justifiable. An inert plastic cloth, Vinyon-N, was successfully used for this purpose in 1952 by Voorhees and his colleagues, but since this material was not readily obtainable in England, the authors chose Orlon for their experiments. Mongrel or greyhound dogs were anesthetized and tubes of Orlon were used as replacements for excised segments of the distal abdominal aorta or as shunts to conduct the blood around an artificial aortic block produced by tying the aorta. All but one of the prostheses remained patent. At the time of writing four of the animals were still alive and under continuing study. Examination of the Orlon tubes at autopsy in the others showed that they become lined with smooth, glistening hyaline collagenous tissue, the innermost layer of which is indistinguishable from intima, and that they are surrounded by a thick layer of fibrous tissue, which encases and grows into the meshes of the cloth. They are well tolerated, and the fact that they retain their tensile strength is of great practical importance, because mere unsupported collagen would be expected to stretch under pressure and with the passage of time. No evidence of calcification was found on x-ray examination in any of the prostheses or their surrounding tissues. These encouraging results led the authors to use similar prostheses in three patients with severe arterial disease. One patient, who had extensive renal lesions, died of renal failure in the postoperative period. The other two were alive, and the prostheses were functioning perfectly five and six months after the operation respectively. One of these patients, who had been forced to stop work because of severe pain in the leg on walking, was able to walk three-quarters of a mile without claudication.

Importance of and Considerations on the Use of Homoplastic Arterial Grafts in Clinical Practice: Late Results in Twelve Cases. L. Provenzale. Policlinico (sez. chir.) 62:65-96 (April) 1955 (In Italian) [Rome, Italy].

Late results are reported on 12 patients in whom homoplastic arterial grafts were used to correct five coarctations of the aorta and seven tetralogies of Fallot. The use of a graft was indicated in the patients with the coarctation because the narrow portion of the vessel was unusually long or because the condition of the vessel's walls suggested that the suture might not hold. The results were encouraging in that the graft made possible a complete functional restoration because a regular arterial lumen, which often is not obtained with an end-to-end anastomosis, was reconstructed. At the time of writing, three patients had resumed their normal activities 24, 19, and 16 months, respectively, after the operation. One patient died after four months following dehiscence of the graft, and another died after nine months from causes independent of the intervention (angina pectoris). There was reason to assume that the graft had been functioning well. In the seven patients with tetralogy of Fallot the graft was resorted to because a short and narrow subclavian artery was present. A homoplastic subclavian artery was used in two patients, a hypogastric artery in four, and an artery that had been removed from the lower lobe of a lung because of multiple cysts in one. These patients were followed from 5 to 22 months. There was evidence of good functioning of the graft in six of them and indication of partial thrombosis of the graft in one. The age of the patients with coarctation of the aorta ranged from 15 to 28 years, that of the other patients from 5 to 25 years. The author discusses the problem of the supply of grafts, the most convenient methods for their preservation, and the best time for their use on the basis of his experience with the functioning of an artery bank, which was established in Rome in 1951.

The Surgical Treatment of Bleeding Esophageal Varices. R. R. Linton. West. J. Surg. 63:366-367 (June) 1955 [Portland, Ore.].

Patients with esophageal varices are in constant danger of death from massive hemorrhage. Gastroesophageal tamponage with an intragastric balloon is the best method of obtaining temporary control of bleeding, when it occurs, but it should not be continued for more than 24 hours because of the danger of ulceration and perforation of the esophagus. Discontinuance of the tamponage is often followed by recurrent hemorrhages which constitute a serious threat to life. Supplementary measures are, therefore, needed to prevent the ruptured varices from bleeding for a longer period, usually several weeks, so that the patient's general health can be improved sufficiently to permit definitive surgical treatment. The method of emergency treatment used during the last four years at the Massachusetts General Hospital has been to secure immediate control of massive bleeding by gastroesophageal tamponage; to restore the patient's blood volume by transfusions as needed; and then to suture or ligate the bleeding vessel through a transpleural transesophageal exposure. Transpleural transesophageal suture was performed 24 times as a lifesaving procedure in 23 patients, with only one operative death. Three patients died about six weeks after the suture procedure, but in the other 19 (83%), 16 of whom are still living, life was substantially prolonged. This is a great improvement over a probable mortality rate of at least 60 to 70% when conservative measures alone are used. The portal bed block responsible for the development of esophageal varices may be extrahepatic, secondary to Banti's disease, or intrahepatic, secondary to cirrhosis of the liver; in either case, the most satisfactory method of definitive treatment is the construction of a splenorenal or direct portacaval shunt. Splenectomy with an end-to-side splenorenal anastomosis is the procedure of choice in most patients. Splenectomy, however, should not be undertaken unless the surgeon is prepared to construct a splenorenal anastomosis at the same operation, because it may be his only opportunity to do so, especially in a patient with an extrahepatic type of portal bed block. Follow-up of 74 patients who survived the construction of a splenorenal or direct portacaval shunt showed that 66 (90%) were alive and for the most part in good health from one to seven years after operation. Mortality rate accompanying bleeding esophageal varices in patients with cirrhosis of the liver is higher than that in patients with Banti's disease, undoubtedly because of the serious effect produced by massive bleeding on an already damaged liver.

General Hypothermia in the Treatment of Massive Hemorrhage: Contribution to Study of Other Possibilities of Its Use in Transfusions of Blood and Substitutes. P. Goffrini and E. Bezzi. Presse méd. 63:847-851 (June 1) 1955 (In French) [Paris, France].

The authors summarize the results of their previous research, in which it was shown that dogs in hypothermia could survive and completely recover from massive, rapid exsanguination. The present series of experiments was performed on 22 dogs, 18 of which were exsanguinated under hypothermia and 4 at normal temperatures. Electrocardiograms, arterial pressures, and respiration were studied to determine the exact mechanism of death from acute anemia. The two pathological factors, hemodynamic imbalance and anoxia, play distinct and separate parts. In the first period of hemorrhage, the changes caused by emptying of the heart and great vessels can be reversed and death prevented by proper fluid replacement; but in the second phase, characterized by progressive decrease in hemoglobin level and hematocrit, there appear disturbances of conduction, excitability, and contractility of the myocardium that are due solely to anoxia. Four practical deductions are made from this work. 1. The clinical application of controlled hypothermia is of great value in the general management of patients in a state of acute hemorrhage, with respect to the consequences of anemic anoxia, though of course it is no substitute for transfusion therapy. 2. Although whole blood is the therapeutic agent of choice in acute hemorrhagic states, substitutes are useful in emergencies resulting from the use of controlled hypothermia. 3. In hemorrhagic states with particular contraindications to total reintegration of the circulating blood volume, it is possible to practice moderate application of a quantitative and qualitative replacement of the lost blood, since the body has a surprisingly high degree of tolerance to exsanguination. 4. In exchange transfusion alternate subtraction and substitution of blood in greater quantities is possible, with consequent simplification of technique and reduction of the inherent dangers of repeated insults to the circulatory equilibrium.

Surgical Management of Massive Acute Upper Gastrointestinal Hemorrhage. C. E. Welch, A. W. Allen and G. A. Donaldson. New England J. Med. 252:921-928 (June 2) 1955 [Boston].

A comparison of death rates from massive hemorrhage from ulcer, treated either medically or surgically, or in combination, in the Massachusetts General Hospital, shows a slight increase from the decade 1923 to 1932 to the present, with a rise in mortality from 13 to 17%, that is, the general death rate from bleeding ulcer has not diminished but has slightly increased, despite a much wider use of surgical treatment. The authors do not believe, however, that early surgical treatment should be abandoned, because this increased mortality is due chiefly to the increasing age of the hospital population and various postoperative complications due to technical errors. Any mortality study of massive hemorrhage must take into account the age distribution of the patients treated. The mortality of all patients treated by either medical or surgical methods ranged from 7% in those under 50, to 29% in those 70 years of age or over. Nevertheless, individual analysis of patients over 80 years of age revealed that they tolerate early surgical treatment better than expectant treatment. The authors believe that a continued lowering of mortality will depend on prevention of postoperative complications and on earlier surgical treatment of patients with massive hemorrhage who are over 60 years of age. The pulmonary complications are the most important cause of the rather high mortality. The most common type of pulmonary complication is aspiration pneumonia. The factors necessary to produce it are a full stomach, or one with an incompetent cardiac sphincter, and depression of the cough reflex. The first of these may be counteracted by keeping the stomach empty during the early postoperative period. Decompression of the stomach can be obtained by the Levin tube, but the authors use a catheter introduced in a retrograde fashion through the efferent jejunostomy loop into the stomach, as described by Allen and Donaldson. This will allow much better clearing of the respiratory tree than can occur when the pharynx is continuously irritated by the Levin tube. Furthermore, this catheter can be tolerated much better and longer than a nasal tube. This technique is especially valuable in elderly, depleted, and very ill patients. Some postoperative deaths have been due to a summation of minor complications. Electrolyte imbalance is another important factor. Continued aspiration of gastric contents and replacement therapy, with intravenous administration of dextrose in isotonic sodium chloride solution may produce a hypochloremic hypokaliemic alkalosis, which may result in death. Replacement of potassium is the most important feature in the prevention of this syndrome. These and other methods designed to prevent postoperative complications were used in 55 patients with hemorrhage from gastric ulcer, and 53 recovered.

Subtotal Versus Total Gastrectomy for Gastric Malignancy: With a Discussion of the Various Technics Advocated in the Operation of Total Gastrectomy. C. J. Hunt. West. J. Surg. **63**:337-343 (June) 1955 [Portland, Ore.].

Total gastrectomy, which is almost certain to be accompanied by a higher operative mortality rate than radical subtotal gastrectomy, should not be generally adopted as the standard surgical treatment for cancer of the stomach. The results will usually be just as good, and many of the disagreeable consequences of total gastrectomy will be avoided, in patients with distal gastric lesions, if an extensive lymphatic dissection is combined with a radical subtotal gastric resection in which a remnant of the fundus is left to serve as a food pouch. Total gastrectomy, however, should be used more frequently for lesions in the midportion of the stomach, and it is certainly indicated for all lesions in the upper half of the stomach, for carcinoma of the linitis plastica type, and when it is necessary for the removal of all accessible cancer. Attempts have been made to overcome the undesirable effects of the operation in a number of ways. A Roux-Y procedure has been used to divert the duodenal contents and so prevent reflux esophagitis, and various segments of the intestinal tract have been transplanted to take the place of the stomach in the hope of maintaining the normal flow of the food content by way of the duodenum. The use of any part of the colon for this purpose is physiologically and anatomically undesirable, because the right colon is an absorptive structure for fluids and the transverse colon, when transplanted, is in an antiperistaltic position in relation to the esophagus and the duodenum. The author, therefore, advocates the use of the jejunum as the best available substitute for the stomach in attempting to overcome the disadvantages of total gastrectomy. His technique consists in using the Roux-Y procedure with the upper jejunum and at the same time constructing a food pouch out of the distal segment of the jejunum. It has been used after total gastrectomy with no operative mortality and excellent results in seven consecutive patients, all of whom have had capacity for a good food intake without discomfort. Few patients who require total gastrectomy can be cured, and in none of these cases was a cure expected. All the patients gained weight, however, and none had any evidence of a dumping syndrome; on the contrary, x-ray films showed an unhurried progressive emptying rate.

Treatment of Chronic Relapsing Pancreatitis. F. L. Coffey, G. F. Woelfel, K. J. David and M. G. Burdette. Am. Surgeon **21**:569-576 (June) 1955 [Atlanta, Ga.].

Thirteen patients, aged 29 to 62 years, with chronic relapsing pancreatitis were treated by celiac ganglionectomy and bilateral splanchnicectomy, with or without sphincterotomy and biliary surgery. In the routine supragastric approach, the gastrohepatic ligament was entered just to the left of the portal vein. The crux of the diaphragm and the aorta at the level of the celiac axis were identified, exposing the celiac ganglions that surround the axis. The greater and lesser splanchnic nerves were isolated as they pass through the crux of the diaphragm to enter the ganglions. Both ganglions were removed by blunt and sharp dissection and the splanchnic nerves were cut 2 to 5 cm. proximal to their entrance into this sympathetic plexus. A different surgical approach to the celiac ganglions, i. e., the retroduodenal-retropancreatic, was devised for use in obese patients and those with a short gastrohepatic ligament, high-lying pancreas, or short celiac axis. In these patients, the lateral peritoneal reflection of the second portion of the duodenum was incised, and the duodenum and adjacent pancreas were rotated anteriorly and to the left, exposing the underlying vena cava and the right renal vein and artery. As the structures were rotated medially, the aorta, the right suprarenal gland and vessels, and the right celiac ganglion were exposed. It is of prime importance to remove all ganglionic tissue with a portion of the splanchnics to insure complete relief of pain, because the celiac ganglions also receive branches from lumbar nerves 1, 2, and 3. Often the superior mesenteric ganglions also are removed to insure relief. Of the 13 patients, the first was operated on two years ago and the last two were operated on a few months ago. It is still too early to evaluate the results in the last two patients. Of the other 11 patients, 9 had complete relief of symptoms, one had partial relief, and one was a therapeutic failure. Two of the nine patients had been in various hospitals over a period of three years and were branded neurotics; they now have been completely free of symptoms since operated on by the authors. Two of the patients showed calcification of the pancreas and six others had biopsies that showed chronic pancreatitis. In patients with obvious chronic pancreatitis, biopsies were not performed because of the added dangers of hemorrhage and formation of fistula. The rationale of the authors' surgical procedure in the management of chronic pancreatitis is: (1) all pain fibers to the pancreatic area, duodenum, and biliary tract have been interrupted by the splanchnicectomy; (2) by celiac ganglionectomy and splanchnicectomy, spasms of the sphincter of Oddi and of the vessels supplying the pancreas have been relieved; and (3) by the splanchnicectomy the blood supply to the pancreas is increased, aiding healing of the organ. Celiac ganglionectomy and bilateral splanchnicectomy, with the correction of biliary disease, if it is present, are effective in treating chronic relapsing pancreatitis, and warrant further investigation.

Prophylaxis of Thromboembolism with Anticoagulants, Particularly Marcoumar. H. J. von Brandis. Chirurg **26**:241-244 (June) 1955 (In German) [Berlin, Germany].

Three men between the ages of 21 and 64 years, who sustained a pulmonary infarction before they underwent a major abdominal operation or between two abdominal surgical interventions that followed one another within a short interval, were given a synthetic heparin preparation (Thrombocid) for three days. On the fourth day treatment with 3-(1-phenylpropyl)-4-hydroxycoumarin (Marcoumar) was started. The first patient had carcinoma of the lesser curvature of the stomach and was operated on three weeks after the pulmonary infarction. The postoperative course was uneventful while prophylactic treatment with Marcoumar was continued. There was no recurrence of embolism, and the patient was discharged in good condition four weeks after the surgical intervention. The second patient had carcinoma of the rectum, and in preparation of a sacroabdominal resection a double current transverse anus was formed in a first-stage intervention. Pulmonary infarction occurred on the 19th postoperative day, immediately before the planned second-stage intervention. The patient was given heparin for three days, and Marcoumar therapy was started on the fourth day. The sacroabdominal amputation was performed on the 33rd day after the infarction. The postoperative course was uneventful, there was no recurrence of the infarction, and the patient was discharged seven weeks after the second surgical intervention. The third patient had appendicitis, was operated on, and sustained a pulmonary infarct on the seventh postoperative day. He was given heparin, and Marcoumar therapy was started on the fourth day. On the ninth day after the infarction a classic strangulation ileus developed that required repeated laparotomy. Marcoumar therapy was discontinued at the time of the operation but was resumed on the fifth postoperative day with cautious regulation of the coagulation values on a median level by small doses of Marcoumar. The patient was discharged on the 17th day after the ileus operation. No embolism recurred. The occurrence of embolism in these three patients emphasizes the difficulty of evaluating surgical patients with regard to the risk of embolism and the necessity of general prophylaxis of thromboembolism. Marcoumar therapy represents a definite progress in this regard as compared with bishydroxycoumarin (Dicumarol) treatment. The selection of patients is done with careful consideration of the function of the liver. Marcoumar therapy is contraindicated in older patients with lesions of the liver and the adrenals or with vascular lesions and in many patients with diseases of the gallbladder and the biliary tract, although in them the risk of thromboembolism is high. Continued control of the blood coagulation values is essential, which makes anticoagulant therapy difficult in small hospitals. Marcoumar prophylaxis can be omitted if examination of the blood coagulation values before the institution of therapy shows delayed coagulation values and low Quick values, respectively. Intensive prophylactic treatment with Marcoumar is indicated in cases with markedly low coagulation values and simultaneous high Quick values.

Vena Cava Inferior Ligation in Congestive Heart Failure: Report on 100 Cases in Five Years. J. Bernath, R. Guillemot, P. Samuel and R. Heim de Balsac. Am. Heart J. **50:**112-128 (July) 1955 [St. Louis].

R. Heim de Balsac has used ligation of the inferior vena cava for the treatment of congestive heart failure since 1949, and since then a large number of patients have received this treatment at the Centre de Broussais in Paris. In this paper the authors review the first 100 patients operated on between April, 1949, and November, 1953. Immediately after the operation, the patient breathes more easily, hepatomegaly regresses, and peripheral edema disappears. However, postoperative complications are frequent. Edema of the lower extremities occurs in the presence of old preexisting inflammatory changes in the veins. The dietetic restrictions for cardiac patients must be continued after the operation. The chief indications for ligation of the vena cava are mitral and combined mitral and aortic disease, particularly in patients in whom rheumatic activity has ceased. Cardiac disorders without valvular lesions and arterial hypertension are also acceptable indications, but the experience of the authors is too limited to assess the results of this operation in congenital heart disease. Absolute contraindications to this operation are cardiac disorders with high output, such as chronic cor pulmonale and thyrotoxicosis, as well as certain valvular lesions, such as advanced aortic stenosis, in which the circulation is greatly restricted. The authors avoid the operation in patients in whom the cardiac lesion is progressive, which is especially likely in patients less than 30 years of age. The mortality was particularly high during the first year after operation (23%). Deaths at this time are partly due to the continuation of cardiac degeneration and partly to vascular accidents. Ligation of the inferior vena cava has no effect on attacks of rheumatic fever or on cerebrovascular accidents. The survival rate after the first year was 60%, after the second 49%, after the third 40%, and after the fourth and fifth years 33%. These values are somewhat distorted by the fact that in the beginning the surgical mortality was excessively high (20% in the first 50 patients, compared with 6% in the second group of 50). The duration of the improvement depends on whether the patient follows the prescribed medical diet, on the changes in his cardiac lesions, on his liver function, on his preoperative kidney function, and on the rapidity with which collateral circulation is established. The last factor appears to destroy the beneficial effects of the operation; cardiac insufficiency reappears and the patient returns t a status similar to that which obtained prior to operation. Nevertheless, ligation of the inferior vena cava seems a satisfactor palliative treatment of intractable cardiac insufficiency, particularly when accompanied by the threat of pulmonary emboli The results corresponded to those obtained by other majo palliative surgical procedures. The authors feel that the functional improvement achieved and the prolongation of life justif the operative and postoperative risks to the patients.

The Significance of Nodular Goiter. J. C. McClintock. Virgini M. Month. **82:**299-301 (July) 1955 [Richmond, Va.].

Of 1,098 patients with nodular goiter operated on by th author between 1949 and 1953, 843 had nontoxic nodular goit and 255 had toxic nodular goiter. Of the 843 with nontoxi nodular goiter, 347 had single nodules, and cancer was fir diagnosed by the pathologist in 27 (7.7%) of these. Four hu dred eighty-six patients had multiple nodular goiters, and canc was first diagnosed by the pathologist in 12 (2.4%). In only patients with nontoxic nodular goiter was a preoperative dia nosis of cancer made and confirmed by pathological examin tion. Of the 843 patients with nontoxic goiter, 614 (73%) h noted or complained about the neck swelling. Two hundr eighty-six (34%) of the 843 patients had mechanical or obstru tive symptoms. Of the 255 patients with toxic goiter, 25 (9.8 had already developed cardiac decompensation and/or auricul fibrillation at the time they were first examined by the auth The damage so produced in even a few patients would ha been avoided by removal of the goiter while it was still in t relatively innocuous nontoxic state. Although among the patie with nodular goiter there were no postoperative deaths, a to of 1,578 thyroidectomies for all types of goiter in all age grou were performed by the author in the course of the same f year period with only one death, and that was caused by cereb hemorrhage. As long as the risk of cancer greatly exceeds risk of surgery, conscientious physicians have no choice but advise excision for nodular goiter.

Comparative Results of Primary Segmental Resection and section After Pneumothorax. A. Marmet, M. Jaubert de Be jeu, G. Weill and others. Strasbourg méd. **6:**302-307 (May) 1 (In French) [Strasbourg, France].

Segmental resection of the lung was carried out in 100 tients with pulmonary tuberculosis, in 30 of whom the indi tion for surgical treatment was unsatisfactory pneumothor Good results were obtained in 97% of the patients with pneumothorax as against 87% of those with pneumothor None of the former patients had incomplete results, while 3.5 of the latter did. In the first group 3% of the patients had p results, as compared with 10% in the second group. Pneum thorax may make the pleura rigid and difficult to free. It m cause fibrous adhesions in the pedicle. It may have an eff on the fibroelastic system of the lung. It may even cause so active lesions to appear dormant. These effects interfere w the success of operation. Postoperatively, complete reexpansi may be difficult and slow in patients with pneumothorax, as was in 43% of the 30 patients in this series, as compared w 17% of the other 70. New bouts of tuberculosis are more f quent in patients who have had pneumothorax. In every pati with tuberculosis an effort should be made from the time he first observed to determine whether the nature of his lesions such as might require resection at some time. If so, pneum thorax is contraindicated. In borderline cases, pneumothor may be tried for not longer than six months but should be aba doned if success is not promptly obtained.

Prognosis of Bronchiectasis After Surgical Resection. R. Ginsberg, J. C. Cooley, A. M. Olsen and others. Surg., Gyne & Obst. **101:**99-102 (July) 1955 [Chicago].

This study was designed to evaluate the results in 255 cas of bronchiectasis treated surgically at the Mayo Clinic in th years 1942 through 1953. Each patient was studied bronch scopically, bronchographically, and pathologically. Acceptab follow-up was possible in 221 of the 255 patients, and the

221 form the basis of this report. These patients had primary bronchiectasis. All cases of bronchiectasis secondary to known foreign body, tuberculosis, tumor, broncholithiasis, or bronchostenosis were excluded. The surgical technique usually consisted of endotracheal anesthesia, posterolateral thoracotomy, individual ligation of hilar structures, and closed temporary intercostal drainage. In selected cases, antibiotics were instilled into the pleural cavity. Postoperatively, antibiotics were used in most cases. Oxygen therapy, blood transfusion, and fluids by vein were used as indicated. The postoperative retention of secretions is to be treated vigorously, and bronchoscopic aspiration is therefore often resorted to. As a result the complete picture of postoperative atelectasis is rarely seen. The authors found that the prognosis for surgical bronchiectasis is good. In this series, 75% of the patients obtained a good result, 21% had a fair or poor result, and 4% died. Residual disease is one of the factors that influences the prognosis adversely. This is the case particularly when it is ipsilateral. New bronchiectasis is usually associated with an unfavorable result, and the progression of residual bronchiectasis probably accounts for a number of unfavorable results. While postoperative complications do not preclude an excellent result, they seem to reduce greatly the chance of obtaining one.

Carcinoma of the Breast: The Status of Present Therapy with Special Reference to a Case Treated by Bilateral Adrenalectomy and Oophorectomy. W. Girdwood and A. L. Jackson. South African M. J. 29:557-562 (June 11) 1955 [Cape Town, South Africa].

Girdwood and Jackson show that radical mastectomy has come into disrepute because it has been used indiscriminately, often in patients whose disease is beyond the reach of the surgeon. The argument in favor of the less extensive or the more radical procedure is dissolved if one definitely classifies cases of carcinoma of the breast as operable or inoperable. The stages described by various authors have not been uniform. The authors suggest a new method of staging and show that, with the concept of hormone-dependent tumors the value of hormone treatment and oophorectomy, or oophorectomy plus adrenalectomy or hypophysectomy, must be considered in relation to the practical clinical problem. Permission must always be obtained before operation so that, if microscopy shows numerous mitotic figures, oophorectomy may be performed at the same time as mastectomy. In all cases deep x-ray therapy should follow mastectomy. In the inoperable group there is possibly some advantage in preoperative deep therapy followed by mastectomy and bilateral adrenalectomy. The authors cite the case of a 51-year-old woman with breast carcinoma and osseous metastases who experienced dramatic improvement with healing of bone lesions after bilateral oophorectomy and adrenalectomy. The primary growth was an undifferentiated carcinoma, a type regarded by some authors as less amenable to this form of treatment. The progress and rationale of endocrine therapy are discussed, and reference is made to hypophysectomy in the treatment of breast carcinoma.

Diagnosis of Masked Pheochromocytomas. W. Mandl. Wien. med. Wchnschr. 105:516-518 (June 25) 1955 (In German) [Vienna, Austria].

Three illustrative cases of masked chromaffinoma (two of masked pheochromocytoma in a 28-year-old woman and a 51-year-old man and one of masked pheochromoblastoma in a 49-year-old man) are described. The terms masked pheochromocytoma and pheochromoblastoma were considered highly suitable because of the presence of atypical symptoms and the absence of typical symptoms in the patients. The woman was admitted to the surgical department of the general hospital of Steyr, Austria, with a diagnosis of cholecystitis. Laparotomy revealed a normal gallbladder but a tumor of the adrenal, which was removed. Intraoperative palpation of the tumor did not cause any increase in blood pressure. Pathological examination of the specimen showed a malignant pheochromocytoma. Reviewed history revealed that the patient as a child had had sensations of heat in the head, redness of the face, tinnitus, and tremor of the hands but these symptoms subsided later on: It appears that the originally typical pheochromocytoma had lost its functional activity after the occurrence of malignancy. If the history had been recorded the first time in an exact manner, a tentative diagnosis of pheochromocytoma could have been made. A duodenal ulcer was suggested by the roentgenologic findings in the 51-year-old man who had abnormal pigmentation of the skin and of the buccal mucosa. Laparotomy revealed a large duodenal ulcer and in addition a tumor of the left adrenal, exploration of which caused systolic blood pressure to rise to 300 mm. Hg. The history did not reveal any subjective symptoms that could have suggested an increase in blood pressure, but later it was discovered that on the occasion of an internal examination a blood pressure of 210/110 mm. Hg had once been measured. The third patient had been hospitalized repeatedly for indefinite upper abdominal pain, but an increase in blood pressure had not been determined. An attack of severe, refractory pain prompted a laparotomy, which revealed a left adrenal tumor that could not be removed because of rapid deterioration of the patient's general condition. Postoperatively extreme sweating of the upper part of the body was observed and the history revealed that hyperhidrosis after the slightest physical and mental exertion had been observed for years. The term atypical pheochromocytoma or pheochromoblastoma was coined for chromaffinomas that are associated with permanent hypertension. The author's cases showed that there are patients in whom hypertension is not present as the guiding symptom or in whom hypertension may not be notable. The term masked pheochromocytoma or pheochromoblastoma, therefore, seems to be appropriate for all nontypical pheochromocytomas or pheochromoblastomas. A tentative diagnosis of chromaffinoma should be considered when only isolated symptoms of the adrenosympathetic symptom complex are present.

The Treatment of Duodenal Ulcer by Vagotomy and Gastro-Jejunostomy. R. L. Holt and A. F. Robinson. Brit. J. Surg. 42:494-502 (March) 1955 [Bristol, England].

The combination of vagotomy and gastrojejunostomy was selected for several reasons, not the least of which was the desire to use the simplest and safest operation on the stomach, so that it could be performed by surgeons of relatively limited experience. From this point of view, gastrojejunostomy appeared to be preferable to pyloroplasty and gastric resection. It had the added attraction that by itself it gives good results in the treatment of duodenal ulcer. Its only serious drawback is that it may be followed by stomal or jejunal ulceration, a complication brought about by the persistent secretion of highly acid gastric juice in the duodenal ulcer patient. This secretion is known to be largely neurogenic in origin and is abolished by vagotomy, so that on theoretical grounds the combination of these two measures appears to be sound. The results reported are those from a conservative series of 243 patients operated on between October, 1947, and July, 1953. During this period all patients with duodenal ulcer referred to the senior author for surgical treatment were treated by vagotomy and gastrojejunostomy except for those who required emergency operations for perforation or hemorrhage. There was only one death in the 243 patients. This patient died three days after operation as a result of continuous diarrhea, cholera-like in its severity, that would not respond to treatment. Analyzing three-year results in 110 patients the authors found that 87% had satisfactory and 13% had unsatisfactory results. They feel that it is a method worthy of consideration. Since it has a low mortality, an absence of serious postoperative complications, and a high proportion of satisfactory results, an increasing number of surgeons recommend this treatment for duodenal ulcer.

A Three to Seven Year Postoperative Evaluation of 76 Patients with Severe Hypertension Treated by Thoracolumbar Sympathectomy. H. A. Zintel, A. M. Sellers, W. A. Jeffers and others. Surg., Gynec. & Obst. 101:48-54 (July) 1955 [Chicago].

The 76 patients on whom this report is based were subjected to thoracolumbar sympathectomy between 1947 and 1951 and were followed up for a minimum of three and a maximum of seven years postoperatively. The patients were operated on for one or more of the following indications: (1) an average diastolic pressure of 120 mm. Hg or more, (2) failure to respond to intensive medical therapy, and (3) evidence of progressive damage to the heart, kidneys, brain, or eyes. Surgery was considered to be contraindicated if: (1) the patient was over the age of 55 years, (2) the patient had been recovering from a stroke or coronary occlusion for less than six months, or (3) the patient had impaired renal function as evidenced by a blood urea nitrogen of over 20 mg. per cubic centimeter or a phenolsulfonphthalein excretion of less than 20% in the 15 minute specimen. A diastolic pressure of 140 mm. Hg or higher was not considered to be a contraindication. Various members of the Hypertension Clinic of the Hospital of the University of Pennsylvania had decided that the patients subjected to operation could not have been helped by any of the types of medical therapy available at the time of operation. One patient died during the postoperative period, and 53 patients are surviving at present, that is, the over-all mortality was 30% in three to seven years. Of the living patients 55% had an excellent or fair blood pressure response. Among the 53 survivors, relief of congestive failure has been obtained in 88%, and of angina pectoris and headache in 93% each. Progressive impairment of renal function has been infrequent. Definite improvement in renal function has not occurred. The survival rates including the operative mortality have been slightly better than those reported by Smithwick, but the data regarding survival indicate that thoracolumbar sympathectomy does extend the life of the patient beyond the length of life that can be expected following nonoperative types of therapy.

Results of Surgical Treatment of Ulcer on Basis of Five-Year Study. N. Blixenkrone-Møller. Nord. med. **53**:837-842 (May 26) 1955 (In Danish) [Stockholm, Sweden].

During the five-year period ending in 1950, 328 patients were treated operatively for duodenal ulcer, gastric ulcer, both ulcer forms simultaneously, cicatricial pyloric stenosis without apparently active ulcer, and peptic ulcer after earlier resection or anastomosis. The results are known in 325 cases. The time of observation was at least four years. Gastric resection, considered the method of choice in gastric or duodenal ulcer, was performed in 152, or 75%, of the 203 cases of duodenal ulcer and in 80, or 95%, of the 84 cases of gastric or gastric and duodenal ulcer, with seven deaths, or 4.3%. The result was fully satisfactory in 40% of the patients; 33% have to avoid certain foods; milder or more severe postcibal distress occurs in 17%; and the remaining 10% have various complaints. In some cases with densely adherent and inflamed duodenal ulcer, gastroenterostomy in combination with vagotomy was done, the results comparing favorably with those after resection. After gastroenterostomy for cicatricial pyloric stenosis in 20 cases, with four deaths, gastrojejunal ulcer developed in two instances. Vagotomy seems to be the method of choice for gastrojejunal ulcer after gastroenterostomy or gastric resection; the operation calls for meticulous care. No reason is seen for changing the operative indications for ulcer. If a patient with duodenal ulcer has had severe symptoms for a couple of years or if two series of treatments for ulcer have been without lasting effect, operation is indicated. In gastric ulcer, operation is called for sooner, not least because of the danger of cancer. If operation is deferred until pyloric stenosis sets in, the results are less favorable.

The Diagnosis of Orthopedic Lesions by Aspiration Biopsy: Results of 1,061 Punctures. C. E. Ottolenghi. J. Bone & Joint Surg. **37-A**:443-464 (June) 1955 [Boston].

If the nature of an osteoarticular lesion cannot be clarified by clinical or roentgenographic examination, Ottolenghi favors biopsy, either by the open method or by aspiration. He reviews his experiences in 1,061 aspirations carried out on 998 patients. The technique employed is that used in the Memorial Hospital in New York. Syringes with metal sleeves or at least metal tips should be used; needles should be 2 mm. in diameter, very acutely beveled and sharp; they should be fixed to the syringe as hermetically as possible. Puncture of the skin should be made with the point of a scalpel. In sclerotic lesions there is a high proportion of failures. Aspiration is made after a vacuum has been produced in the syringe by withdrawal of the piston. Punctures were made in nearly all of the bones of the skeleton, wit the exception of those at the base of the skull and the vertebra between the 1st and the 10th thoracic. The results were con sidered positive when the diagnosis could be established, doubt ful when the diagnosis could not be confirmed and had to b verified by some other means, and negative when the diagnosi could not be made. Of the 1,061 aspirations 895 gave positive 45 doubtful, and 121 negative results. A table, which lists 87 positive diagnoses confirmed by open biopsy, by surgical e posure of the lesion, or by the clinical course, shows that th majority of diagnostic aspiration biopsies were made for malig nant tumors. The method is simple, carries no risk to the pa tient, and does not exclude other methods of diagnosis. It i particularly useful in deep locations such as the vertebral bodie or the pelvis.

Surgical Treatment of Spondylolisthesis Without Spine Fusio Excision of the Loose Lamina with Decompression of the Ner Roots. G. G. Gill, J. G. Manning and H. L. White. J. Bo & Joint Surg. **37-A**:493-520 (June) 1955 [Boston].

The prevalent concept of the cause of symptoms in spond lolisthesis is based upon the belief that, because of the defe in the pars interarticularis of the fifth lumbar vertebra, there instability at the lumbosacral junction and thereby a tenden for progressive forward slipping of the vertebral body. Fusi has been the accepted treatment. The concept of instabili however, fails to explain the clinical course often seen in the patients. The authors observed a young woman in whom a seve sciatica developed following a hyperextension injury. The x-ra showed a first-degree spondylolisthesis. A herniated disk w suspected but not found on exploration of the fifth lumb interspace; however, it was noted that on hyperextensi the mobile lamina of the fifth lumbar vertebra rocked distal causing traction on the first sacral nerve roots. For this reas the fifth lumbar lamina was excised and a lateral fusion w performed. The patient had considerable relief of the low extremity pain. Shortly thereafter another patient with spond lolisthesis was seen, with sciatic radiation and with eviden of compression of the fifth lumbar root. On removal of t mobile lamina of the fifth lumbar vertebra, the fifth lumb root was seen to be compressed by a mass of fibrocartilagin tissue at the defect in the pars interarticularis of the fifth lu bar vertebra. After decompression of the roots by removal the fibrocartilaginous mass, a lateral fusion was perform There was immediate relief of the sciatic pain and of the neu logical symptoms. A third patient with a similar condition w treated in an identical manner with relief. Meanwhile, in t second patient local back pain again developed, as well coccygodynia and pain in the lower extremities associated w tightness in straight-leg raising. Reexploration showed that t bone grafts had slipped medially, causing formation of adhesio of bone to the dura. Because of this complication, and on t basis of limited experience with excision of the inferior articu processes without fusion in arthritic patients, it was decided th in the next patient a decompression procedure alone should done and later, if necessary, a lateral fusion could be perform with greater safety. This operation was first performed on physician in June, 1950. There was relief of the pain both the back and in the lower extremities, and the patient resum full activity in three weeks. Since then, in 18 cases surgery h consisted solely of removal of the loose lamina with compl decompression of the fifth lumbar and the first sacral roots. five other cases, in which fusion operations had failed to res in either fusion or relief of symptoms, excision of the fusi mass and of the inferior articular process with decompressi of the roots has given relief. In one other case, despite a co ventional and solid fusion, the symptoms persisted until t fibrocartilaginous mass was removed. Surgical exploration co sistently revealed the presence of a fibrocartilaginous mass the defect in the pars interarticularis of the fifth lumbar vertebr in some instances this was larger on one side than on the othe but it corresponded in general with the neurological finding The authors show that their concept of the pathomechanics this condition answers all that is not explained by the preval concept of instability at the lumbosacral junction.

NEUROLOGY & PSYCHIATRY

Dihydroergotamine in Treatment of Trigeminal Neuralgia. K. Decker. Deutsche med. Wchnschr. 80:887-889 (June 10) 1955 (In German) [Stuttgart, Germany].

While studies on the pathogenesis of trigeminal neuralgia, which the author carried out in 1948 and 1949, provided no new viewpoints, interesting therapeutic observations were made. The trigeminal pain disappeared or subsided in some patients while they were being treated with dihydroergotamine, but all attempts to elucidate the mode of action of this drug failed. When Simon in 1949, and Bodechtel in 1950, described favorable results with dihydroergotamine in trigeminal neuralgia, the author followed the further fate of his patients. Fifty patients who had been treated with dihydroergotamine could be reached in 1953 to 1954 for a follow-up inquiry. These patients had trigeminal neuralgia with typical attacks of tic douloureux. The ages of the 27 men and 23 women ranged from 40 to 75 years. At the onset of treatment the pain had existed for an average of four years, but all patients had been temporarily free from attacks, possibly as the result of treatment with vitamin B, with antirheumatic measures, or with roentgen irradiation; also foci of infection had been removed from the teeth or the sinuses; and removal of a branch of the nerve, coagulation of the ganglion or blockage of the sympathetic had been performed in some of the patients. The dihydroergotamine therapy was begun with 5 drops given three times daily and was increased by one drop given three times daily until the daily dose reached a maximum of 20 drops three times a day. Increase in dosage was stopped at levels at which the pain showed improvement, was continued at this level for from two to four weeks, and was then gradually reduced. Treatment was continued for an average of two months. The pains disappeared in 24 patients after the first treatment, but a year later only 10 patients were still free from pain, and after four or five years only four patients were still free from pain. The author concludes that about one third of the patients experienced prolonged relief from trigeminal neuralgia once or several times as the result of treatment with dihydroergotamine.

Results of BAL Therapy in Vascular and Inflammatory Neuropathies: Clinical Contribution on Twenty-Five Cases. G. Romualdi and L. Calabrese. Clin. terap. 8:282-299 (March) 1955 (In Italian) [Rome, Italy].

BAL (2, 3-dimercaptopropanol) was used in the treatment of 4 patients with polyneuritis or neuritis of alcoholic, toxic, or diabetic nature, 14 with post-thrombotic encephalomalacia and cerebrospinal arteriosclerotic syndrome, 5 with encephalomyelitis, and one each with multiple sclerosis and chronic progressive external ophthalmoplegia of long standing. This is the first report in the world's literature on the use of BAL in the treatment of cerebral thrombosis and diffuse cerebrospinal arteriosclerosis. The drug was given in daily doses of 0.1 to 0.2 gm. for total doses ranging from 1 to 9.9 gm. in one or more courses of treatment. There were no side-effects, and the renal function and the blood picture were not altered. The conditions treated benefited regardless of whether the origin of the damage to the nervous cell was vascular or inflammatory. Complete resolution of the motor paralysis was obtained in three patients, and good results (without complete recovery) were obtained in one patient with polyneuritis or neuritis. The results were satisfactory in six and fair in four patients with post-thrombotic encephalomalacia and cerebrospinal arteriosclerosis, whereas the condition remained unchanged in four patients of this group. Of the five patients with encephalomyelitis, three improved and the improvement was still present 5, 6, and 18 months later respectively. One patient benefited slightly and one not at all. Improvement was still present in the patient with multiple sclerosis three years after the therapy was carried out. Ptosis diminished, and active motility of the eyelids became almost normal in the patient with the eye condition in whom all previous therapies had been of no avail. The improvement was still present after 90 days. Although spontaneous recovery is possible in all neurological conditions, there was evidence that BAL did influence the condition of most of these patients, acting if not as the determining factor at least as the factor that speeded up improvement and recovery. As a rule, the sooner the therapy was instituted after the onset of the condition, the better the results. It is suggested that BAL be combined with anticoagulant (heparin) therapy when used to treat cerebral thrombosis of recent onset.

Complications of Chlorpromazine Therapy in 800 Mental-Hospital Patients. J. Lomas, R. H. Boardman and M. Markowe. Lancet 1:1144-1147 (June 4) 1955 [London, England].

This report is based on 800 patients, 260 men and 540 women, treated with chlorpromazine. The patients were not questioned about any untoward effects; hence any complications noted were either a result of spontaneous complaint by the patients or observed by the nurses and doctors. Though all types of mental disturbances were treated, the great majority of patients had acute or chronic psychoses. The dosage varied, but the most commonly adopted plan was to start with 150 mg. daily and to increase rapidly to 300 mg. daily. The less seriously disturbed patients received smaller doses, and a few patients had their dosage increased to 800 mg. daily. The duration of treatment varied from a few weeks to several months. The great majority of patients received the chlorpromazine orally and received ambulatory treatment from the start. A minority underwent electroconvulsion therapy concurrently, and most patients were receiving barbiturate sedation. No other form of therapy could account for the toxic reactions. The authors divide the complications into side-effects and toxic reactions. The side-effects were: tachycardia, hypotension, dryness of mouth, constipation, nausea, vomiting, frequency of micturition, Parkinsonian-like syndrome, and local irritation at the site of injection. Both subjective complaints and observed disturbances were much less common in disturbed psychotic patients than in others, and the more chronic the psychosis the less was the incidence of side-effects. Hypotension is the only one of the side-effects requiring special precautions and then only in the aged and those with cardiovascular dysfunction. Of the 59 toxic reactions (7.4% of the 800 patients), 48 occurred among the 540 women (8.9%) and only 11 among the 260 men (4.2%). The toxic manifestations were: jaundice, blood dyscrasias, skin reactions, edema, pyrexia, and epileptic fits. Jaundice and blood dyscrasias may prove fatal and are absolute contraindications to continuing treatment with chlorpromazine. Previous liver dysfunction may predispose to jaundice and therefore should also be regarded as a contraindication to such treatment. With the exception of epileptic fits, the time of occurrence of all toxic manifestations had a definite relationship to the duration of treatment but not to the dosage at the time or to the total dosage of chlorpromazine. In view of this finding and the occurrence of eosinophilia in some cases, the toxic reactions are probably due to sensitization. Epileptic fits occurred mainly in postleukotomy patients, and in only one case were no predisposing factors detected. Therefore chlorpromazine may have epileptogenic properties that may cause manifest fits in susceptible people.

Extracellular Hyperosmolarity After Cerebral Lesions. P. Anthonisen, T. Hilden and A. C. Thomsen. Nord. med. 53:713-718 (May 5) 1955 (In Danish) [Stockholm, Sweden].

Attention is called to a symptom complex originating after cerebral injury and consisting of high serum values of chloride and sodium and slight elimination of these ions. The 46 cases of the syndrome published since 1937 are tabulated. The cerebral lesions are of widely different kinds including contusions, vascular catastrophes, tumors, encephalitis, postoperative sequels, insulin shock, and sulfathiazol intoxication. Most of the lesions in question are in the frontal lobes, hypophysis-hypothalamus region or both. The following hypothesis is set forth: A cerebral lesion of the osmoregulating mechanism causes dehydration, tending to a reduction of the organism's water content and reduction of the blood volume. This will stimulate the normal volume-regulatory mechanism of the organism and entail an active salt retention. Evaluation of the prognosis is difficult. The cerebral lesions in themselves have a high mortality. Of the 46 patients, 33 died, 11 survived, and the fate of two is not known. So powerful an electrolyte shifting as often occurs is believed to play an important part in the mortality. In the surviving patients the disturbance of osmoregulation seems as a rule to have been reversible. Besides the usual treatment of the different lesions and complications most authors have given abundant salt-free fluids. Treatment with a mercury diuretic tried by Persson in two instances apparently brought improvement in one. Some cases are possibly adapted for treatment with the artificial kidney.

GYNECOLOGY & OBSTETRICS

The Stein-Leventhal Syndrome. I. F. Stein. West. J. Surg. **63:** 319-323 (June) 1955 [Portland, Ore.].

Secondary amenorrhea, a male type of hirsutism, sterility, hypoplasia of the uterus, and bilaterally enlarged, symmetrical ovaries are the signs and symptoms most consistently found in patients presenting the Stein-Leventhal syndrome (bilateral polycystic ovaries and sterility). This syndrome, which occurs in both married and single women, mostly between the ages of 17 and 30, is apparently endocrine in origin, although its exact cause is still unknown. Pregnancy may occur in the married women during the evolutionary phase of the syndrome, before the ovaries have become completely polycystic, but with this rare exception sterility is the rule. A presumptive diagnosis can often be made on the basis of the history alone in typical cases, in which normal puberty and early adolescence with either regular or irregular cycles are succeeded after a few years by periods of amenorrhea that become progressively longer; in a great many cases the amenorrhea becomes absolute. The presumptive diagnosis can be substantiated in about 50% of the cases by the routine bimanual examination (rectal examination in single girls). Gynecography (pneumoroentgenography), which usually obviates the need for exploratory laparotomy, should be used to establish the diagnosis in cases in which the results of bimanual examination are inconclusive. Bilateral ovarian wedge resection, which is extremely simple and can be done through a Pfannenstiel incision in less than 30 minutes, is the treatment of choice for patients with this condition. Ovulation usually occurs spontaneously after the operation, and there is no indication for routine postoperative endocrine or x-ray therapy. Sterility was successfully relieved by this procedure in 57 (89%) of 64 married patients complaining of infertility: they have had a total of 120 pregnancies with 97 live births (four sets of twins) and six patients undelivered.

Indications for Hysterectomy. W. P. Hutcherson and A. H. Bullard. J. Tennessee M. A. **48:**219-225 (June) 1955 [Nashville, Tenn.].

The authors review 205 hysterectomies, which they performed between 1951 and 1954. They believe that the surgeon should be equally proficient in the abdominal and vaginal approach. Total abdominal hysterectomies were performed in 104 patients, vaginal hysterectomies in 93, and subtotal abdominal hysterectomies in 8 patients. In the age group between 20 and 39 abdominal hysterectomy was most frequently performed, because it is indicated for lesions that are most frequently found in this age group such as fibromyomas, ovarian tumors, pelvic inflammatory disease, and endometriosis. Between the ages of 40 and 59 abdominal and vaginal hysterectomies were performed with about equal frequency, and from ages 60 to 69 vaginal hysterectomies were performed more frequently, because in women of these ages relaxation due to childbirth is the most frequent indication for hysterectomy. Of the 104 women who were subjected to abdominal hysterectomy, 52 had abnormal bleeding; in 25 of these, curettages were performed prior to hysterectomy, and seven malignant lesions were found. Curettement was performed in 21 others at the time of hysterectomy, but no malignant tumor was found. Of the 93 women subjected to vaginal hysterectomy 44 had abnormal bleeding. Previous curettages had been performed in 14 patients, revealing adenocarcinoma of the endometrium in one. Sixty-seven curettements were performed at the time of the vaginal hysterectomies. Hysterectomy seems to be the only treatment for patients with uncontrolled dysfunctional bleeding and incapacitating dysmenorrhea if childbearing need not be considered. Among the
gynecologic indications for abdominal hysterectomy, fibrc
oma topped the list, accounting for 48 of the 104 cases. O
indications of uterine origin were adenomyosis, dysfuncti
bleeding, adenocarcinoma of endometrium, carcinoma in
of the cervix, and invasive carcinoma of the cervix. Fort
the 93 vaginal hysterectomies were performed for repair
other disease, and 35 were performed primarily for relaxa
due to childbirth, that is, cystocele, rectocele, and prolaps
varying degrees. Thus 80.6% of the vaginal hysterectomie
cluded anterior and posterior repair, whereas only six (or 5.
of the abdominal operations were accompanied by repar
measures. No deaths resulted in the 205 hysterectomies, b
few minor complications such as cystitis, cuff infections,
temperature elevations of undetermined origin occurred.

Methylandrostenediol in Treatment of Sexual Frigidit
Women. A. Migliavacca. Riv. ostét. e ginec. prat. 37:6
(Feb.) 1955 (In Italian) [Milan, Italy].

Methylandrostenediol was used in the treatment of 27 f
women. It was employed instead of testosterone becaus
virilizing activity is almost negligible. The doses that in te
terone therapy gave good results—three 100 mg. injectio
two to three day intervals after the menstrual period—were
effective with this drug. Good results were obtained in 1
these patients when the dose was increased threefold. De
the administration of this large quantity, hirsutism,
changes, and hypertrophy of the clitoris were not observe
soft hair appeared on both forearms of one patient who
received 600 mg. of the drug, but it disappeared spontane
after three months. In all of the patients the anabolic actic
the drug was already evident 15 days after the therapy
started, and weight gains ranged from 1.7 to 4.3 kg.
menstruations remained unchanged except for three patien
whom the menses had a tendency to diminish in qua
Euphoria and a greater psychodynamic activity was experie
by the patients, and some vague neurovegetative disturba
of unknown origin were also favorably influenced. The relat
poor aphrodisiac action of methylandrostenediol with re
to that of testosterone is in part compensated by the fact
larger doses of the former can be used without the ons
virilizing side-effects. The drug is indicated in the treatme
female sexual frigidity when testosterone therapy has faile
when the eventual risk of its virilizing effects is to be avo

The Present Status of Human Male Infertility. J. MacL
Am. J. Obst. & Gynec. 69:1256-1267 (June) 1955 [St. Loui

In the past decade several studies on semen quality in ap
ently normal men and in cases of infertility have provid
more rigid definition of male infertility. The author bel
that the range of normal male fertility is much wider than
been supposed and that the sperm count per se is not the
important factor. The figure of 20 million cells per cubic c
meter is suggested as the lower level of male fertility. The p
tial of male fertility above a certain level of sperm count i
related to rising counts. There is a close relationship bet
quality of sperm motility and fertility potential. The motilit
the spermatozoa may be considered as a compensating fa
in the presence of a low sperm count. When discharged dir
into a receptacle and examined immediately, the seminal
is a coagulum in the meshes of which the spermatozoa
immobile. There is debate as to whether the nonmotile stat
the spermatozoa at this stage is physical in the sense that
are unable to move against the great viscosity of the coagul
seminal fluid or whether they lacked motility at the moment
were projected into mixture with the fluids of the seminal vesi
and prostate. The visual evidence is in favor of already m
cells being inactivated by the physical state of their new
vironment. When the coagulum is examined microscopic
during the early stages of liquefaction, two distinct phases
be seen, one in which the spermatozoa are immobilized in
coagulum but show vigorous tail movement, and the othe
fluid or liquefied phase in which, now free, they show vigor
progressive activity. Another important aspect of seminal qua
at the time of ejaculation is that most of the spermatozoa
expelled in the first third of the ejaculate. Since we are acc
tomed to thinking of the efficacy of the sperm count in ter

of count per unit and not total count, the importance of this massing of the spermatozoa in a relatively small forward portion of the ejaculate may have significance. The passage of the spermatozoa from the male to the female genital tract under physiological conditions is a rapid process and probably depends on the concentration per unit volume of spermatozoa in the first portion of the ejaculate and may be limited by the resistance of the cervical mucus.

Fractures Resulting from Eclamptic Convulsions: Review of Literature, Case Reports, and Medicolegal Implications. J. R. Reinberger and W. F. Mackey. Am. J. Obst. & Gynec. 69:1167-1173 (June) 1955 [St. Louis].

Reports on eight cases of fractures resulting from eclamptic convulsions were found in the literature. The authors describe a case of their own, in which convulsions during postpartum eclampsia resulted in a fracture of the neck of the humerus and slight compression of the body of the eighth thoracic vertebra. This patient instituted suit for neglect, charging that the eclamptic convulsions and fractures should have been prevented by proper medical supervision. Judgment was rendered against the defendant, but was reversed in a higher court. Eclampsia cannot be prevented in certain patients, and this patient had no symptoms indicating that postpartum eclampsia would occur. Questionnaires were sent to 70 medical schools in the United States inquiring about fractures due to eclamptic convulsions that had not been reported in the literature. Replies were received to 39 of these questionnaires. A total of 1,479 cases of eclampsia was observed at these 39 institutions over a period of 10 years, and two fractures due to eclamptic convulsions and two dislocated jaws were observed. The authors conclude that fractures are one of the rarest and least known complications resulting from eclampsia. They are similar to those found after convulsive therapy. These fractures are most common in patients with postpartum eclampsia and are chiefly those of the long bones and of the vertebral column. All patients who have had eclamptic convulsions should have a complete radiological examination before leaving the hospital, to be repeated in four weeks if any symptoms compatible with bone injury appear. For medicolegal reasons, this x-ray examination should be carried out before discharge from the hospital. All pregnant patients who present themselves to the obstetrician in the last four weeks of gestation should receive careful supervision on account of possible concealed toxemia, which might result in eclamptic convulsions and thereby give rise to medicolegal disputes.

Incidence of Prematurity in Relation to Maternal Nutrition. P. C. Jeans, M. B. Smith and G. Stearns. J. Am. Dietet. A. 31:576-581 (June) 1955 [Chicago].

The dietary habits of 404 pregnant women of low income, living in a predominantly rural midwestern state, were investigated. The present report concerns the incidence of prematurity in the infants born to these women, in relation to the maternal diets. Few of the women had had prenatal care or advice. They were admitted to the obstetric ward of the University Hospital about two weeks before delivery. The infants were considered prematurely born if the birth weight was less than 2,500 gm. (less than 5.5 lb.). The dietary patterns of the mothers showed a consistently high intake of white bread and potatoes. Milk intake was surprisingly low, especially so for a dairy state, and both the variety and the quantity of fruits and vegetables eaten were limited. In addition to potatoes, only carrots, apples, and tomatoes were eaten with any frequency. The meat intake tended to follow the financial status. Maternal diets were especially deficient in calcium and protein. Enrichment of bread and flour prevented severely deficient intakes of iron, thiamine, and riboflavin in many women. Potatoes were the chief source of ascorbic acid. Tomatoes and carrots provided ample carotenoids. Caloric overindulgence was far more common than inadequacy of caloric intake; the latter, when it occurred, was usually because of persistent nausea and vomiting. Obesity was common, even in the women under 30 years of age. Frequently, diets that were adequate in a majority of the 10 nutrients studied achieved that status only because the quantities of the chosen foods eaten were excessive. The mothers were divided into five groups according to their protein intakes. Group 1 received 85 gm. or more of protein daily; group 2, 70 to 85 gm.; group 3, 60 to 70 gm.; group 4, 50 to 60 gm.; and group 5, less than 50 gm. It was found that lowest birth weights, low vitality, and large numbers of deaths in the newborn infants occurred among those born to the most poorly nourished mothers. The incidence of prematurity rose sharply with the decrease in the nutritional status of the mother. Among the better-nourished women, premature delivery tended to be associated with frequency and total number of pregnancies and with multiple birth. Among the less well nourished, the incidence of prematurity showed less relationship to number or frequency of pregnancies.

Vaginal and Urinary Cytology in Threatening Abortion and in Abortion. F. Gagliardi and A. Cortella. Riv. ostet. e ginec. prat. 37:95-108 (Feb.) 1955 (In Italian) [Milan, Italy].

Vaginal and urinary sediment smears were studied in 22 cases of threatening abortion, 10 of which could not be prevented, and, before the rupture of the pregnant tube, in 2 cases of extrauterine abortion. Besides the qualitative evaluation of the cells, the acidophilic and karyopycnotic cell levels of both smears were studied and the qualitative estrogen level was deduced from them. Although there was, from the morphological standpoint, a certain parallelism between the two smears, the number of acidophil and karyopycnotic cells in the urinary smear was always lower than that in the vaginal smear. The vaginal smear technique gives a more reliable prognosis in threatening abortion than does the urinary sediment smear technique. The difference between the smears of patients in whom abortion could not and those of patients in whom abortion could be prevented was qualitative rather than quantitative. As a rule, the presence of decidual-like cells or of the postabortion-type cell with a decrease or disappearance of intermediate cells, the presence of perinuclear vacuoles accompanied by a high estrogen level indicate unfavorable prognosis, although in some cases of unavoidable abortion the findings may be almost normal. The so-called pregnancy cells are scarce and almost entirely missing from the smears of patients in whom the abortion cannot be prevented. The authors state that the vaginal smear study should be preferred to that of the urinary sediment smear. This may be useful in cases in which the vaginal smear cannot be obtained because of a great loss of blood or because other factors are present. No conclusion is drawn on the two cases of extrauterine pregnancy.

Accumulation of Radioactive Iodine by Human Fetal Thyroids. R. E. Hodges, T. C. Evans, J. T. Bradbury and W. C. Keettel. J. Clin. Endocrinol. 15:661-667 (June) 1955 [Springfield, Ill.].

The thyroid glands of fetuses from nine women in whom therapeutic abortion was induced were examined for radioactive iodine (I^{131}) content. The mothers had each been given 500 μc. of I^{131} about 24 hours prior to operation. The presumed ages of the fetuses ranged from 6½ to 15 weeks. It was found that the human fetal thyroid has the ability to accumulate demonstrable amounts of I^{131} by the 12th week of gestation. It is a matter for conjecture whether this accumulation of iodine is enough to warrant prohibition of radioactive iodine therapy of maternal thyrotoxicosis. A thyrotoxic mother was given a therapeutic dose of I^{131} at a stage of pregnancy when the fetus presumably could accumulate iodine, and she was delivered of a normal baby near term. One year later the child was normal in height and weight and was in good health. Other such cases have been reported. The lack of fetal thyroid damage may be due to the fact that the quantity of I^{131} was insufficient to be harmful. In the present series the uptake was demonstrable only by radioautograph. Furthermore, in thyrotoxicosis the maternal thyroid has a much greater affinity for iodine and hence might reduce the amount available to the fetus. In the present study the maternal uptake was 69% in the thyrotoxic patient as compared with 22 to 46% (average 30%) in the euthyroid women. It is also possible that the concentration of circulating thyroxine is elevated in thyrotoxicosis and, according to Peterson, thyroxine can readily pass the placental barrier, thus depressing fetal uptake of radioiodine. Further studies are needed to determine the amount of radioiodine accumulated at any given age by the human fetus and the sensitivity of the fetal thyroid to irradiation.

PEDIATRICS

Mucoproteins in Rheumatic Disease of Infancy. B. Fantuzzi and C. Neuhaus. Minerva pediat. **7:**478-481 (April 14) 1955 (In Italian) [Turin, Italy].

The serum mucoprotein concentration was studied in 8 healthy children, 8 children with various febrile conditions, and 13 children with rheumatic disease. In all of these except one, the mucoprotein determination, which was made the first time at the onset of the condition before commencing therapy, was repeated from two to five times at intervals of 10 to 15 days. Therapy consisted in the oral administration of aminopyrine (Pyramidon) alternating with that of salicylate, which was also given rectally. The serum mucoprotein level varied from 4.3 to 7.8 mg. per 100 cc. in the healthy children. In those with rheumatic disease, it was markedly increased, varying from 9.8 to 15.3 mg. per 100 cc. The erythrocyte sedimentation rate was increased in 10 of these children, and, generally, the higher the serum mucoprotein level, the higher the sedimentation rate; this ratio was not constant, however. The serum mucoprotein level did not differ markedly in the children with and those without cardiac involvement. As the children improved, the sedimentation rate gradually dropped to normal values. The mucoprotein level also decreased progressively, but at a much slower rate. In the eight children with nonrheumatic febrile conditions in whom the sedimentation rate was increased, the serum mucoprotein concentration, although higher than normal, did not reach the values that were found in the children with rheumatic disease. The mucoprotein level in the serum proved to be a more sensitive, and therefore a more reliable, indicator of the disease's activity than the sedimentation rate. The authors state that this laboratory test, which is easy to perform, may well become a valuable diagnostic and prognostic tool in some febrile conditions of infancy.

Cyclic Vomiting as a Form of Epilepsy in Children. J. G. Millichap, C. T. Lombroso and W. G. Lennox. Pediatrics **15:**705-714 (June) 1955 [Springfield, Ill.].

Thirty-three children in whom a diagnosis of cyclic or periodic vomiting was made did not present evidence of intrinsic disease of the abdominal or other viscera, and the cause of the symptoms had not been determined. They were then studied for evidence of a cerebral origin of the recurrent, paroxysmal autonomic symptoms. In addition to cyclic vomiting, seven of the children had a history of grand mal or psychomotor seizures, two had experienced a convulsion in early life, and five had occasional loss of consciousness either with or apart from the period of vomiting. The clinical features of patients with uncomplicated cyclic vomiting and of those with associated grand mal or psychomotor seizures were similar. The vomiting was periodic in type and of prolonged duration. It was associated with ketosis and frequently with dehydration. The average age at onset of the periodic symptoms was four years. Abdominal pain occurred in about half the patients. Abdominal epilepsy or abdominal migraine replaced the cyclic vomiting in seven patients and migraine headaches supervened in five, in all 36% of the patients. Nine children had a history of eczema, asthma, or hay fever. Behavior disorders were present in 11 children (33%), 4 of whom were mentally retarded. Other episodic symptoms, in order of frequency, were: fever, constipation, diarrhea, paresthesia, enuresis, tetany, visual disturbance, rash, and joint pain. The electroencephalograms of all patients were in some respect abnormal. Evidence of damage to the brain was definite in 14 children (42%), and suggestive in 6. Six had been born prematurely; 9, and possibly 13, had experienced head trauma or anoxia at birth; 7 had a history of postnatal trauma, associated in 3 with unconsciousness; and 5 had a history of a severe infection (measles, postvaccinal encephalitis, meningitis, or pneumonia) that preceded the onset of cyclic vomiting. Fourteen of the patients without history of convulsions or psychomotor seizures were given regular doses of the anticonvulsants Dilantin, phenobarbital, or Mysoline. Dilantin proved the most effective in the prevention of attacks, while tablets or suppositories of ergotamine tartrate with caffeine were useful in their alleviation. On the basis of all these findings, all 33 children could, in the authors' opinion, qualify for a diagnosis of autonomic epilepsy.

The Pulmonary Manifestations of Fibrocystic Disease of the Pancreas. P. A. di Sant'Agnese. Dis. Chest **27:**654-667 (June) 1955 [Chicago].

Between 1939 and 1954, cystic fibrosis of the pancreas, a generalized hereditary disease of children in which the pancreas, the lungs, the sweat glands, and frequently the liver are affected, was observed by the author in 291 children. Only 21 were hospitalized in the first five years, but 270 were admitted to hospital in the last decade of the period studied. This increased incidence is a reflection both of greater recognition of the disease and of the advent of effective antibiotics, which greatly prolong the life span. The basic nature of the disease is not known, but it is probable that all exocrine glands are affected in this condition. A variable degree of bronchial and pulmonary involvement is a virtually constant feature of the disease, usually dominates the clinical findings, and determines the fate of the patient. Cystic fibrosis of the pancreas is the commonest cause of chronic nontuberculous pulmonary disease in the pediatric age group. Cystic fibrosis of the pancreas differs from othe diseases of the lungs in that the basic phenomenon leading t respiratory involvement is a mechanical one, i. e., failure to re move bronchial mucus, which perhaps is abnormal in its physico chemical characteristics. This results in widespread and sever bronchial obstruction and predisposes the patients to secondar infection. Bronchial obstruction may thus be considered as th primary and cardinal manifestation of the pulmonary componen of fibrocystic disease of the pancreas. The causative agent usually Micrococcus (Staphylococcus) pyogenes var. aureus. the 291 children with this disease, 133 died. Of those still livin 29 were between the ages of 10 and 18 years; some of the were doing well. Early diagnosis and administration of ant biotics such as penicillin and streptomycin and of the broa spectrum antibiotics, such as oxytetracycline, chlortetracyclin and tetracycline, before the respiratory infection causes perm nent damage to the bronchi, in addition to a high-protein, low fat diet with adequate amounts of the liposoluble vitamins, adde pancreatic extracts, and liberal amounts of salt in hot weathe offer the best hope of tiding these patients over into late chil hood when the manifestations of this disorder seem to becom milder.

Isoniazid in Tuberculous Peritonitis of Childhood. H. Shuk and S. Awwaad. A. M. A. Am. J. Dis. Child. **89:**685-688 (Jun 1955 [Chicago].

Fifteen children with different types of tuberculous peritonit were collected from the outpatient department of the Children Hospital at Abbassia, Egypt, and were hospitalized for trea ment with isoniazid. The children ranged in age from 3 to years. Seven patients had the ascitic form of tuberculous pe tonitis, 7 had the fibrocaseous type, and one child had tab mesenterica (tuberculosis of the mesenteric glands). Some those with the ascitic and the fibrocaseous types also had tuberc losis of the mesenteric glands. Isoniazid was used also in thr children of one family, in whom abscesses had developed at th site of BCG vaccination with draining sinuses and region lymphadenitis. In the first 10 of the peritonitis patients isoniaz was given in daily doses of 5 mg. per kilogram of body weigh in the other 5 the dose was raised to 10 mg. per kilogram weight. Treatment with isoniazid was continued for from 6 10 weeks, and in some children *p*-aminosalicylic acid was give after the 10th week. Complete rest, good diet and tonics we employed in addition to the isoniazid therapy. Twelve of th 15 patients with tuberculous peritonitis, including all those wi tuberculous ascites and tuberculosis of the mesenteric gland were cured, and no recurrences were observed in a follow-u period of 10 to 20 months. Of the seven patients with the fibro caseous type of tuberculous peritonitis, four were cured withi six to eight weeks and the other three showed great improve ment. Fever when present subsided within one week, and th erythrocyte sedimentation rate showed a progressive declin reaching normal or very near normal levels by the end o treatment. The body weight showed an increase in 13 cases an remained stationary in the other two. Associated extra-abdomina tuberculosis was also very favorably influenced with isoniazid but in one patient cervical lymphadenitis with sinuses recurre after six months. The dramatic healing of the local complications following BCG vaccination gives a new indication for soniazid therapy. The fear of local complication need no longer deter BCG vaccination. Neither the low nor the higher doses of isoniazid caused toxic reactions; however, no significant improvement in the clinical condition was induced by the high dosage to recommend its application.

Hemodialysis of the Uremic Child. F. M. Mateer, L. Greenman and T. S. Danowski. A. M. A. Am. J. Dis. Child. **89**:645-555 (June) 1955 [Chicago].

The report is concerned with extracorporeal hemodialysis, which was used eight times in five children. In all instances an artificial kidney of a modified Alwall type was used. This machine consists of three stainless steel screens that hold a flattened 50 ft. (15.2 m.) length of 1⅛ in. (2.9 cm.) cellophane tubing in a 32 liter bath that is thermostatically controlled. Heparinized blood (3 to 5 mg. heparin per kilogram body weight intravenously) from the patient's radial artery flows through connections of nonwetting plastic tubing to a roller pump, through the cellophane tubing, again through the pump, and back to the patient's saphenous vein by way of a bubble trap and clot catcher. The dialyzing bath had the following composition: sodium 142 mEq. per liter, calcium 7 mg. per 100 ml., chloride 107 mEq. per liter, bicarbonate 37 mEq. per liter, glucose 255 mg. per 100 ml., and, when indicated, potassium 4 mEq. per liter. The patients ranged in age from 7 to 15 years. All patients were either stuporous or confused. During dialysis, which lasted from 109 to 793 minutes, the patients became more alert. Temperature, pulse rate, and blood pressure changed little in this period. Minor fluctuations in blood pressure in the third dialysis of one of the patients were readily corrected by addition of blood from the reservoir. Respiration in the three patients who were overbreathing became normal. Pulmonary edema, which existed in one patient, diminished. Urine flow, which was present only in two prior to application of the artificial kidney, continued during dialysis. Increased amounts of sedation were needed in one patient to control the convulsive seizures during dialysis. Three of the patients died. Two patients, one with acute tubular necrosis, a second with chronic glomerulonephritis, are living seven months after dialysis, the first with normal renal function. Indications for hemodialysis in uremic patients include anuria of five or more days' duration, potassium intoxication, pulmonary edema, intractable acidosis, and hyponatremia. Severe hemorrhage is the only contraindication. In view of the difficulty in assessing elements of reversibility of renal failure in chronic states, more frequent use of dialysis is indicated in these situations.

DERMATOLOGY

A New Treatment for Seborrheic Dermatitis: A Clinical Investigation. F. I. Ball. A. M. A. Arch. Dermat. **71**:696-698 (June) 1955 [Chicago].

Vancide-benzethonium solution was used to treat 98 patients with seborrheic dermatitis. Vancide 89 (N-trichloromethylmercapto-4-cyclohexane-1,2-dicarboximide) has been used in the agricultural chemical field as a fungicide, where it is known as Captan. In order to make this compound readily usable by human subjects, it was incorporated into an aqueous alcoholic lotion. This lotion referred to as Solution 105-6, contains, in addition to 0.085% of Vancide 89, 0.060% of benzethonium (Phemerol), which was added to broaden the bactericidal scope of the preparation. Of the 98 patients treated, the disease was classified as severe in 28, moderate in 52, and mild in 18. Of the 28 with severe disease, 20 were completely controlled, 6 were improved, and 2 unimproved. Of the 52 with moderate disease, 39 were completely controlled and 12 were improved; in one an allergic reaction occurred. Of the 18 with mild disease 15 completely cleared up, 2 were improved, and one failed to show any appreciable improvement. The 98 patients included 6 with atopic dermatitis and 10 with acne vulgaris, in all of whom the seborrhea of the scalp was brought under control. Four patients with the so-called "cradle-cap" type of seborrheic dermatitis were completely controlled. Eight patients with otitis externa were treated. The condition in four was completely controlled, but the others were not improved. No increased oiliness of the scalp was noted at any time following the use of this medication. It did not discolor gray or light-colored hair.

Treatment of Chronic Lupus Erythematosus with Atabrine and Chloroquine. R. B. Stoughton. Illinois M. J. **107**:299-301 (June) 1955 [Chicago].

Chloroquine was used in 25, and quinacrine (atabrine) in 18 patients with chronic lupus erythematosus. Half of the patients receiving chloroquine showed definite improvement, while the others experienced little or no improvement. Twenty-three of these 25 patients had already received treatment with other drugs, such as gold, bismuth, pantothenates, vitamin E, or carbon dioxide, without significant change in the lesions. It was most impressive when a chronic discoid patch of lupus erythematosus, after years of resistance to all treatment, suddenly underwent resolution when chloroquine or quinacrine were administered. After these drugs were discontinued, many patients relapsed to their former status, but readministration again resulted in a favorable response in most cases. Chloroquine is preferable to quinacrine, because it is less toxic, does not stain the skin yellow, and is at least as effective in therapy. Maintenance doses may have to be given to the majority of patients in order to prevent recurrences. From his own experience and from various reported studies, the author deduces that for the average adult with chronic lupus erythematosus an initial dose of 750 mg. of chloroquine can be given for 10 to 14 days and can be succeeded by 250 to 500 mg. per day for an indefinite period.

Chlorquinaldol (Sterosan) in Dermatologic Therapy. J. C. Murphy. Rocky Mountain M. J. **52**:530-532 (June) 1955 [Denver].

Chlorquinaldol (Sterosan) is a recent addition to the oxyquinoline derivatives. A series of 124 patients with a variety of pyogenic and eczematous dermatoses were treated either with 3% chlorquinaldol in an ointment base containing petrolatum and lanolin, or with 3% chlorquinaldol in a vanishing cream base. The preparation was given to patients in 1-oz. tubes or jars with directions that it be applied generously to the affected skin areas at least twice a day. A soft cotton-cloth dressing was advised in most cases. For patients with pyogenic disorders, cleansing twice daily with mild soap and water was directed. For eczematous and pruritic lesions, soap was forbidden, but gentle cleansing with a bland vegetable oil was permitted, when necessary. If additional therapy was used, a clinically comparable case was selected for treatment with chlorquinaldol alone. Treatment was discontinued after seven days in a few patients, in whom no response was elicited or who experienced irritation. When possible, "paired comparison" tests were used, a different topical medication (e. g., tar, antibiotic, or antipruritic) being used on the opposite side. Eczematous disorders existed in 89 of the 124 patients and included among others dyshidrosis, housewives' eczema, nummular eczema, and infantile eczema. A second group of 17 patients had disorders with an infectious component such as pyoderma (including impetigo), paronychia, furunculosis, balanitis, external otitis, and intertrigo. The third group comprised 18 patients with miscellaneous disorders such as lichen simplex, burns, dermatitis venenata, dermatitis or ulcer due to stasis, flexural neurodermatitis, and seborrheic dermatitis. Clearing or great improvement of the lesions was noted in 87.1% of all patients. There was improvement without cure in an additional 6.5%, and no change in 4%. Three patients with irritation were observed (2.4%), but there was no instance of sensitization.

Effect of Reserpine in Certain Dermatological Conditions. V. Panaccio. Union méd. Canada **84**:672-674 (June) 1955 (In French) [Montreal, Canada].

Reserpine (Serpasil) was administered to 28 patients with dermatological conditions in which psychic factors were prominent. Excellent results were achieved in 9 of 15 patients with psoriasis with 0.25 mg. of reserpine given three times a day, but follow-up has not been long enough to prove whether these results are permanent. The four patients with urticaria and the two with lichen planus were remarkably benefited; the action of the drug in these diseases was much more rapid than in psoriasis. In the six patients with chronic eczema, results were practically nil except in one patient, who is maintained in the asymptomatic state by 0.25 mg. of reserpine three times a day; symptoms recur immediately the drug is withheld. The one patient with prurigo also used reserpine as maintenance therapy. The commonest side-effects of reserpine administration are nasal congestion, somnolence, nightmares, and weight gain. One patient had nocturnal tremor with chattering of the teeth. These effects disappeared either with the passage of time or on the reduction of dosage from 0.5 to 0.25 mg. three times a day. The author noted two previously unreported reactions to reserpine: generalized eczematous dermatitis and asthmatiform paroxysm with facial edema and congestion. A patient who was receiving 5 mg. a day of the drug manifested a Parkinsonian syndrome (paralysis agitans) with hand tremor at rest and hypersalivation. Discontinuation of reserpine therapy caused the disorder to disappear.

UROLOGY

Clinical Application of Hemostasis with Muscular Tissue in Nephrotomy: Late Results in Twelve Cases. A. Acquati. Gior. ital. chir. **11:**425-439 (May) 1955 (In Italian) [Naples, Italy].

Acquati reports the results obtained in 12 patients in whom nephrotomy was performed and in whom, for hemostatic purposes, a strip of muscular tissue secured from the lumbar incision was placed into the operative wound and sutured. Nephrotomy was done in most of the patients to remove stones from the calices; in a few patients with so-called essential hematuria, it was merely an exploratory operation. The placing of the graft into the wound makes it possible to reduce the number of sutures and aims at obtaining good hemostasis and preventing parenchymal hemorrhages. The hemostatic effect is due partly to tamponing of the vessels and partly to the biological action of the muscular tissue. Parenchymal hemorrhages never occurred in these patients. A macroscopic hematuria was seen in some of them in the immediate postoperative days, but it was never severe, lasted six to eight days, and disappeared gradually in a few days. The presence of the muscular tissue in the wound did not interfere with the process of recovery and did not cause side-effects. Tests performed in the immediate postoperative course and again before the patients were discharged revealed prompt and complete restoration of renal function. This was still present several years later, thus indicating that the functional structure of the renal parenchyma was only slightly impaired by the connective tissue, which slowly replaced the grafted muscular tissue that underwent necrosis. Calcium formation in the parenchyma or the excretory cavities was not evident in the roentgenograms. It was possible to make histological studies of one of these kidneys that was removed two months after the nephrotomy because of pyelonephrosis. They revealed that the recovery process in the wound was good with minimal impairment of the parenchyma. No regenerative attempt on the part of the grafted muscular tissue was apparent, and calcification process was not present in the renal parenchyma.

Study of Renal Function by Means of Clearance of p-Aminohippuric Acid and Mannitol. A. Conti and C. Danese. Minerva nefrol. **2:**23-28 (Jan.-March) 1955 (In Italian) [Turin, Italy].

The method used by the authors to study the renal function by means of the clearances of *p*-aminohippuric acid and mannitol is presented. After a 12-hour period of fast and rest and one hour before commencing the test, the patient is given 500 to 700 cc. of water, and 10 cc. of blood are withdrawn for the hematocrit determination of the so-called white plasma corpuscles, namely, of those substances that interfere with the assay of mannitol because they have the same chromatic reaction. Then *p*-aminohippuric acid and mannitol are administered either in a single injection or by continuous perfusion. When the fir
mode of administration is used, 6 to 8 cc. of a 20% solutic
of *p*-aminohippuric acid and 50 cc. of a 20% solution of mar
tol are injected over a 10-minute period. Fifteen minutes aft
the injection was started, the bladder is emptied (with the p
tient standing, if possible) by introducing a catheter, which
left in situ. At the 20th minute, and then again at the 30
minute, 10 cc. of blood are withdrawn; at the 25th minute, ar
then again at the 35th minute, the bladder is emptied and washe
with 50 cc. of isotonic sodium chloride solution, and both tl
urine and the lavage solution are collected. When the substanc
are administered by the continuous perfusion method, 3 to
cc. of a 20% solution of *p*-aminohippuric acid and 50 cc. of
20% solution of mannitol are given slowly. This is follow
by the perfusion of an isotonic sodium chloride solution contai
ing *p*-aminohippuric acid in a 0.5% ratio and mannitol in
2% ratio. The blood and the urine are collected in the sar
manner as in the previous method. To estimate the tubular e
cretory capacity, the authors inject very slowly 50 to 80 cc.
a 20% solution of *p*-aminohippuric acid. At the 10th minu
and then again at the 40th minute, the bladder is empti
and washed and the urine and lavage solution are collecte
at the 25th minute, 10 cc. of blood are withdrawn. Ha
burger's technique is followed for the blood and urine ass
of mannitol and *p*-aminohippuric acid, and the photomet
determination of the two substances is made with Liet
apparatus. The authors used the above methods to study t
renal clearances of the two substances in patients in whc
there were no alterations of the cardiovascular and uropoie
systems. They found that (1) with the continuous perfusi
method of administration the glomerular filtrate fluctuated t
tween 110 and 135 cc. per minute and the renal plasma flc
between 560 and 820 cc. per minute; (2) with the single inj
tion method the glomerular filtrate ranged from 105 to 140 c
per minute and the renal plasma flow from 570 to 750 cc. p
minute; and (3) the *p*-aminohippuric acid tubular excretc
capacity was of 81 to 88 mg. per minute.

The Present Status of Renal Angiography. E. W. Riches. B
J. Surg. **42:**462-470 (March) 1955 [Bristol, England].

Riches says that the use of organic iodine preparations inste
of sodium iodide has abolished nearly all the dangers of re
angiography. Diodone, 70%, has been used in more than 2
patients at Middlesex Hospital. There are two routes of approa
to the abdominal aorta for angiography, the lumbar and t
femoral. After a trial of both methods the author favors t
lumbar route as being easier, quicker, and less prone to failu
or complications. The femoral route is indicated if an aor
aneurysm is suspected. The general effects of injecting 30 r
or even 60 ml. of diodone 70% rapidly into the circulati
must be foreseen. Some patients are sensitive to iodine, a
before doing an excretion pyelogram a sensitivity test shou
be done with a small amount of diodone. When this work w
started, the author considered that the main indication for a
aortogram was when one kidney failed to function on excreti
urography and its ureter could not be catheterized for the pu
pose of a retrograde pyelogram. That is still an important gener
indication, but the scope of the investigation has been widene
The first 100 patients in whom the author employed renal angio
raphy included 21 with renal new growths, 18 with hydr
nephrosis and hydrocalicosis (localized dilatation of a calix), 1
with renal cysts, 14 with congenital anomalies, 12 with hem
turia or pain, 9 with tuberculosis, 7 with nontuberculous i
flammation, and 4 with calculous disease. Renal angiography
a safe procedure, and the technique can be mastered fairl
easily. It can be done in any general hospital that has a goo
diagnostic x-ray department. It is an essential part of the in
vestigation of a space-occupying lesion in the kidney, of hydro
nephrosis, of congenital anomalies, and of any condition fo
which partial nephrectomy is contemplated. It is often desirabl
in suspected renal hypertension. The contraindications to its us
are iodine sensitivity and uremia. Its scope will be increased by
improvements in film-changing mechanisms and in x-ray tech
nique generally. It does not replace the standard well-tried
urological investigations, but is complementary to them.

BOOK REVIEWS

Diseases of the Thyroid Gland. By Samuel L. Gargill, M.D., Assistant Clinical Professor of Medicine, Harvard Medical School, Boston, and Mark Falcon Lesses, M.D., Instructor in Medicine, Harvard Medical School. (Reprinted from 'Oxford' Loose-Leaf Medicine with same page numbers as in that work) Cloth. $12. Pp. 839-964 (375). Oxford University Press, 114 Fifth Ave., New York 11, 1955.

The authors have given a comprehensive and well-written résumé of the present status of thyroid disorders. All aspects of the subject are covered comprehensively with an adequate presentation of the underlying physiological facts essential for an understanding of the modern management of these diseases. The authors present their material clearly and succinctly with well-selected illustrations and bibliographic references. The typography is excellent, but the binding is not commensurate with the general high quality of the book. This book may be recommended to the reader desiring an up-to-date coverage of the modern concepts of the pathogenesis, diagnosis, and treatment of disorders of the thyroid.

Fluoroscopy in Diagnostic Roentgenology. By Otto Deutschberger, M.D., Assistant Clinical Professor of Radiology, New York Medical College, New York. With introduction by Frank J. Borrelli, M.D., F.A.C.R., Professor of Radiology, New York Medical College. Cloth. $22. Pp. 771, with 888 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1955.

This book is divided into two parts. Part 1 starts with the history and development of fluoroscopy. For the benefit of the beginner, the author describes fluoroscopes in detail, covering their operation, the shifting of the tube and screen, and various methods of control of the field of vision. Safety regulations are described. The various types of fluoroscopic image are discussed, also methods, procedures, and the results obtained. The newer electronically amplified fluoroscopic images are included, with description of the physical processes involved and the construction of these units; this chapter covers the entire subject of electronically operated equipment, giving a complete list of references. A clinical evaluation of fluoroscopy compares it with radiography, giving the advantages and disadvantages of both. Various types of lesion that are found are discussed. Foreign body localizations are explained in detail; there is a valuable chapter describing foreign bodies and how they may be localized and discussing various methods of marking to make for ease of surgical removal. Part 2 is devoted to clinical considerations, including lesions found in various parts of the body and the technique of using contrast mediums to visualize various organs under fluoroscopic study. Various parts of the anatomy are taken up in detail with discussion of the technique used in their visualization and of the lesions found in this type of study. The fluoroscope probably is most widely used in the study of the chest. The chapter on thoracic fluoroscopy goes into detail in describing the methods used to study the heart, lungs, and thoracic cage, the various shadows seen, and the differentiation of normal and abnormal conditions. Many physicians are probably unfamiliar with the many ways in which the fluoroscope may be used in the study and differential diagnosis of various types of abdominal diseases. The chapter covering this aspect of the subject should be of particular interest to the beginner and the medical student. The final chapter on the use of the fluoroscope in studying the extremities describes the types of lesion found and the definite aid of the fluoroscope in fractures. The appendix is a compilation of fluoroscopic findings, methods of reporting, and the various forms that might be used in reporting fluoroscopic studies. The The index of authors is most complete, and there is also a subject index. This book should be required reading for any group doing fluoroscopy and especially for beginners. The chief objection to the book is that all the figures are negative instead of positive prints.

A Primer of Electrocardiography. By George E. Burch, M.D., F.A.C.P., Henderson Professor of Medicine, Tulane University School of Medicine, New Orleans, and Travis Winsor, M.D., F.A.C.P., Assistant Clinical Professor of Medicine, University of Southern California Medical School, Los Angeles. Third edition. Cloth. $5. Pp. 286, with 281 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadephia 6, 1955

This third revision continues the high standards of its predecessors and includes the current accepted knowledge of the complex problems of electrocardiography. Its title is a little misleading due to the use of the word "primer," since the subject is dealt with in a comprehensive way. The word "primer," however, seems to have been used to emphasize the aim of the authors to supply the user with fundamental knowledge and understanding of the scope and limitations of clinical electrocardiography. This goal has been accomplished satisfactorily. The text is profusely illustrated with well-selected figures that aid the user in its understanding. Controversial matters have been omitted, apparently in the belief that they would be unsuitable for an introductory guide. In addition to the initial chapter on the principles of electrocardiography, the material is presented in sections dealing with analysis of the various components of the electrocardiogram and their clinical significance, the precordial leads, the disorders of the heartbeat, and the clinical applications of electrocardiography. An appendix comments on the triaxial reference system, the electrical axis, average norms of the several intervals and waves of the tracings, the P-R interval, duration of QRS, S-T segments, Q-T interval, relation of cycle length to heart rate, and criteria of the truly diagnostic features of the tracing such as the definite evidences of myocardial disease, strongly suggestive evidences of the latter, and certain findings not in themselves abnormal. A key for recording the electrocardiogram ends the text. The volume is well suited to its purpose, well printed and bound, and should be of real help to the experienced cardiologist as well as the beginner in electrocardiography. It can be recommended without reservation.

The Behavior of Pulmonary Tuberculous Lesions: A Pathological Study. By E. M. Medlar, Chief Pathologist, Division of Tuberculosis, New York State Department of Health, Hermann N. Biggs Memorial Hospital, Ithaca, New York. Cloth. Pp. 244, with 136 illustrations. [Hermann M. Biggs Memorial Hospital, Ithaca, N. Y., n.d.]

This work is a summary of Dr. Medlar's experience in the study of the pathology of tuberculosis. Tuberculosis is still with us, although the pattern of its appearance, morbidity, and mortality has changed since 1922 when the Hegeman Memorial Laboratory was opened at Mount McGregor, N. Y. Despite the splendid record of achievement in reducing the death toll from tuberculosis, the disease still ranks among the important public health problems in this country. The skill, precision, and soundness of this work are reflected in the carefulness of the descriptions and beauty of the illustrations. A familiarity with this work should increase the clinician's confidence in the accuracy of inferences he may draw from clinical data and objective findings. Medlar sought to understand the dynamics of tuberculosis, and, if the contents of this book are sufficiently controversial to stimulate further effort to solve the problem, its purpose will have been accomplished. Discussion of views of other writers is purposely avoided, since this is not intended to be a textbook.

The chapters cover a statement of the problem, the experimental approach, autopsy studies of human pulmonary tuberculosis, preliminary discussion of resected specimens, behavior of the parenchymal tuberculous lesion, a study of resected minimal tuberculosis, bronchial lesions in tuberculosis, tuberculosis and bronchiectasis, bacteriological observations, and a reexamination of the problem. The volume is a reprint of original copy appearing in the March, 1955, issue of the *American Review of Tuberculosis* (vol. 71 [part 2] no. 3). This outstanding contribution is the result of patient endeavor.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

Lehrbuch der praktischen Orthopädie. Von Dozent Dr. Walther Aberle, et al. Herausgegeben von Ph. Erlacher. Cloth. $24.50. Pp. 549, with 764 illustrations. Verlag Wilhelm Maudrich, Spitalgasse 1b, Vienna IX; Bonn, 1955.

This textbook of practical orthopedics presents the fundamental ideas taught by Dr. Spitzy. The authors are recognized authorities in the field of orthopedics and are former students of Dr. Spitzy. There are sections on special orthopedic techniques, orthopedics in children, adolescent orthopedics, adult orthopedics, and amputations. The book is concerned with investigation and recognition, prevention, and treatment of all deformities and disturbances in body mechanics. It is primarily the result of observations made during the last 50 years. Congenital deformities, rickets, tuberculosis, and paralysis were the chief concern of orthopedics in the early part of the century. World War I produced an extraordinary number of wounds and amputations. There has also been a tremendous increase in automobile and industrial accidents in the last 50 years. As a result, techniques for care of amputations have been rapidly developed. The results of World War II were similar to those of World War I, but there was a far greater number of casualties. During the recent decades, disorders due to mechanical strain and tension have greatly increased. Arthroses and hypertrophic arthritis have become a more important orthopedic problem due to the longer life span. Tremendous advances have been made in surgery for orthopedic conditions in England, America, Germany, and Austria. Advances in all other branches of medicine have also influenced modern orthopedics. There is a discussion under children's orthopedics of club feet, torticollis, and scoliosis. The importance of the intervertebral disk as an etiological factor in scoliosis is discussed. An excellent chapter is devoted to dysplasias of the hip with conservative and surgical treatment. There is a complete description of poliomyelitis, spastic paralysis, and tuberculosis. Epiphysial disturbances and osteomyelitis are considered under adolescent orthopedics. The arrangement of the material is practical and concise. The book is amply illustrated with clear and interesting plates. This is a textbook that gives a view of modern German orthopedics. It is a credit to the authors as well as to their former professor, Dr. Spitzy.

Housing the Aging. Edited by Wilma Donahue. With foreword by Everett J. Soop. Cloth. $3.75. Pp. 280. University of Michigan Press, Ann Arbor, 1954.

This book is a comprehensive and well-documented study and report on housing of the aged (everybody is aging). It is a cooperative effort of the university, the Michigan State Medical Society, the Housing and Home Finance Agency, and the Committee on Aging and Geriatrics of the Federal Security Agency. It recognizes and brings into focus the importance of the care of the aged in health and during illness. Prolonged illness in the aged is truly a catastrophic condition. The report is somewhat critical, and justly so, of the unwillingness of the general hospital to do its share in caring for this group. It brings out the fact that most of the aged are cared for in the home and reports on the limited number of groups devoted to the home care of these people. It also points up the dangers of accident to these people, not only in the home but also in hospitals and nursing homes. It recommends changes and corrections, such as housing them on one floor and with non-skid flooring and safeguards in bathrooms. The necessity for these changes is recognized by all who are familiar with this problem. A thorough outline of the economic problems is presented, as well as suggested methods for improvement. All in all it is an excellent review and deserves a prominent place as a reference book.

Airborne Contagion and Air Hygiene: An Ecological Study of Droplet Infections. By William Firth Wells. Cloth. $6. Pp. 423, with 85 illustrations. Published for Commonwealth Fund by Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London E.C.4, England, 1955.

This volume represents, in large part, the results of studies on droplet nuclei and their relationship to the spread of disease. The author has been engaged in these investigations for almost 20 years and presents a clear and informative picture of the dynamics of the spread of air-borne infection. Part 1 describes the physics and chemistry of droplets and droplet nuclei and the biology and related physics and chemistry of infection and disinfection. The physiology and parasitology of droplet nuclei contagion are presented. The experimental work that led to the final conclusions is explained and described with clarity. Part 2 is concerned with principles and methods of prevention of infection primarily through an understanding of the forces that are responsible for the spread of air-borne disease. The principles of sanitary ventilation are defined and presented in an understandable manner. The entire book is well written and all terms that may be at all unfamiliar are defined in advance. Good use is made of photographs, tables, and drawings. This book should be of interest not only to the epidemiologist but also to all persons who are concerned, in any way, with preventive medicine.

The Spine: A Radiological Text and Atlas. By Bernard S. Epstein, M.D., Chief, Department of Radiology, Long Island Jewish Hospital, New Hyde Park, N. Y. Cloth. $16.50. Pp. 539, with 721 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1955.

This rather complete roentgenologic textbook treats the vertebral column as a separate entity. It is one of the more important contributions dealing with the spine since the publication of "The Vertebrae" by George and Leonard in 1929. The first chapter describes the normal development and anatomic variations of the vertebral column that serves as a guide to the understanding of the abnormal spine. The following chapters contain an excellent correlation of radiological and clinical findings of all the diseases that affect the spine, primarily or secondarily. The smooth continuous writing affords easy reading, while the numerous illustrations add much to the descriptions. The author's wide experience, plus a most complete and recent list of references, makes this book a valuable radiological treatise.

Practitioners' Conferences Held at the New York Hospital-Cornell Medical Center. Volume I. Edited by Claude E. Forkner, M.D., F.A.C.P., Professor of Clinical Medicine, Cornell University Medical College, New York. Cloth. $6.75. Pp. 411. Appleton-Century-Crofts, Inc., 35 W. 32nd St., New York 1, 1955.

This volume presents, for the first time in book form, a collection of the panel discussions conducted at Cornell as a series of informal clinical conferences open to all physicians of the greater New York area. Some of the discussions have been published in *New York Medicine*, and those included in the book have been further revised and edited to bring them up to date. The topics include such subjects as influenza and primary atypical pneumonia, present status of corticotropin and cortisone, disorders of feet, and home care of patients with acute poliomyelitis. Discussions encompass pathogenesis, diagnosis, prevention, and treatment of certain important diseases. The comments of the panel participants are reproduced in their original dialogue form, supplemented by a summary and list of pertinent references at the end of each discussion. No index is provided, but the topics are readily accessible from the table of contents. General practitioners, specialists, senior medical students, interns, and residents should find this book helpful in gaining additional knowledge of some of the important problems that confront the physician.

Modern Trends in Ophthalmology: Third Series. Edited by Arnold Sorsby. Cloth. $12.50. Pp. 346, with 111 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1955.

This book is divided into six sections. In the first newer developments in anatomy, physiology, and optics are dealt with by outstanding experts in the use of the electron microscope, in current biochemical problems, and in newer aspects of physiological optics. The second section covers diagnostic procedures most important of which are ophthalmoscopy of the extreme fundus periphery and slit lamp microscopy of the posterior segment of the eye. The third section discusses clinical and experimental pathology. About half of the book is devoted to the fourth and fifth sections covering clinical aspects and treatment. The chapter on ocular aspects of diffuse collagen diseases is particularly well written and clearly explained. There are 53 contributors, some of the outstanding ophthalmologists in the world, who write authoritatively on their particular development or interest in a special phase in ophthalmology.

A Textbook of Medicine. Edited by Russell L. Cecil, M.D., Sc.D., and Robert F. Loeb, M.D., Sc.D., LL.D., Bard Professor of Medicine, Columbia University, New York. Associate editors: Alexander B. Gutman, M.D., Ph.D., Professor of Medicine, Columbia University, Walsh McDermott, M.D., Livingston Farrand Professor of Public Health and Preventive Medicine, Cornell University, and Harold G. Wolff, M.D., Professor of Medicine (Neurology), Cornell University, New York. Ninth edition. Cloth. $15. Pp. 1786, with 201 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1955.

The popularity of this classic textbook is attested by the fact that, since its first appearance in 1927, it has undergone eight revisions. As in the past, the authors have combined the physiological and biochemical aspects of disease with the actual description of the disease. Thirty-nine subjects not covered in previous editions have been added; many of the old sections have been rewritten by new contributors; and some sections have been transferred to a more appropriate grouping. The imposing list of 172 contributors includes the outstanding authorities in the various fields covered. The book is well illustrated, with some of the plates reproduced in color. The two-column page makes for greater ease in reading. References are included at the end of each subject. The indexing is exceptionally complete. This edition should easily gain the enthusiastic reception accorded to its predecessors.

History of the Second World War: United Kingdom Medical Series. Editor-in-Chief: Sir Arthur S. MacNalty, K.C.B., M.A., M.D. The Army Medical Services. Administration: Volume II. Edited by F. A. E. Crew, F.R.S. Cloth. 65s. Pp. 564, with 39 plates. Her Majesty's Stationery Office, P. O. Box 569, London, S.E. 1, England, 1955.

This book is the second and last volume of the British official medical history of World War II. It is concerned chiefly with the organization and medical administration of various special services, some of which were new departures while others were already in being when war started. The volume was edited by Prof. F. A. E. Crew under the supervision of an editorial board appointed by the British government. The first chapter deals with the Army Nursing Service; then comes the chronicle of the Army Hygiene Service, which did much to prevent epidemics of infectious disease in the British Army. Chapter 5 deals with the creation and evolution during the war of the Army Dental Service. The remaining chapters tell of the Army Blood Transfusion Service, the Army Psychiatric Service, the Army Pathology Service, the Army Radiological Service, the Army Ophthalmic Service, and medical provision for the Auxiliary Territorial Service. These historical accounts, no doubt, provide lessons from the past, some of which should be of value in the future.

Hematology. By Cyrus C. Sturgis, M.D., Professor of Internal Medicine, University of Michigan Medical School, Ann Arbor. Second edition. Cloth. $19.50. Pp. 1222, with 78 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1955.

This heavy, bulky, expensive book contains a great deal of information. The historical introductions to most of the chapters are excellent. The modern medical student seems to be in a sort of present-day vacuum from which his teachers often make no effort to extricate him. He knows what the situation is now, but what went before and how difficult it was to reach the present situation are rarely taught. In this isolated environment, dominated as it is by the necessity of accumulating as much information (with as little culture) as possible, modern-day miracles, whether they be vitamin B_{12}, penicillin, or cortisone, are taken for granted. Except for the historical data, Sturgis' textbook is orthodox and singularly lacking in imagination and in the development of concepts but nevertheless straightforward and descriptive. It gives information without stimulation. There is too much reliance on the "literature," often quoted at great length and often uncritically. Although this new edition purports to be up-to-the-minute, some of the older quotations from the literature are retained, despite newer information that may have made them obsolete. Far more information about many of the subjects discussed can be obtained through consulting a number of monographs containing more critically evaluated and authoritative data.

Bedside Diagnosis. By Charles Seward, M.D., F.R.C.P., Physician, Royal Devon and Exeter Hospital, Exeter, England. With foreword by Sir Henry Cohen, M.D., D.Sc., LL.D., Professor of Medicine, University of Liverpool. Third edition, Cloth. $4. Pp. 408, with illustrations. Williams & Wilkins Company; Mount Royal and Guilford Aves., Baltimore 2; E. & S. Livingstone, Ltd., 16 and 17 Teviot Pl., Edinburgh 1, Scotland, 1955.

The author has attempted to treat the problem of diagnosis in internal medicine from a standpoint of interpreting the significant symptoms. This is a refreshing approach and one that should receive more emphasis in our medical schools. Rather than listing the more important diseases and then enumerating the prominent symptoms, the author bases his book around 20 of the most common and significant complaints of the patients. He devotes a chapter to each symptom and discusses, in turn, the pathological physiology, a suggested diagnostic approach, and then the various diseases or disturbances of function that will produce the symptom. He does not neglect the fact that many of these symptoms may at times be of a psychosomatic nature and devotes an additional chapter to this aspect. The discussions are brief and to the point, and the edition is printed in a convenient pocket size. It should be of use not only to the student but also to the practicing physician, who is constantly faced with the problem of selecting the significant symptom and then making the correct interpretation.

Les maladies de l'anus et du canal anal. Par Pierre Hillemand, médecin de l'Hôpital Tenon, Alfred Bensaude, et Jean Loygue, chirurgien des hôpitaux de Paris. Avec la collaboration de Jean André et Edwin Sidi, médecin-chef du Service de dermato-allergie de la Fondation Rotschild. Cloth. 3400 francs. Pp. 283, with 57 illustrations. Masson & Cie, 120 boulevard Saint-Germain, Paris, 6e, France, 1955.

The authors of this splendidly written and well-illustrated manual believe that, although rectal disease is well documented, information pertaining to diseases of the anus and of the anal canal is sparse, at least in France. The purpose of the book, therefore, is to fill this gap. Gastroenterologist, surgeon, and dermatologist have collaborated in the production of this volume. Part 1 includes anatomy, physiology, and symptomatology; part 2 pertains to anal spasm and anal atony; and part 3 deals with anal diseases. The illustrations, some in color, are excellent. To avoid possible confusion, the reader must realize that the authors include the perineal portion of the rectum in the term "anal canal." This work, therefore, necessarily involves some rectal problems, a circumstance that does not, however, detract in the least from the stated objective of the book. Every physician who is interested in the better management of anorectal disease should find this manual a valuable addition to his library.

Principles of Animal Virology. By F. M. Burnet, Director, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia. Cloth. $10. Pp. 486, with 35 illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1955.

The widespread interest in poliomyelitis vaccine has made the appearance of this book most timely. The author states, "One can agree wholeheartedly with the current decision of American authorities to use formalin-killed virus as the vaccine for the first large scale test, but still retain the opinion that, in the long run, the more natural method will prove the most effective and will eventually be adopted as the definitive method for the prevention of poliomyelitis." Much space is given to such subjects as morphology, cellular structure, and variation of viruses, but the practical application of knowledge available is not neglected. In the final chapter on classification and nomenclature, the viruses causing disease in animals and man are divided into five groups—Rickettsiales, Poxvirus, Herpesvirus, Poliovirus, and Myxovirus. The author has had a long experience with virus investigations and has cited numerous references to the work of nearly a thousand other workers from many countries. The bibliography is excellent.

QUERIES AND MINOR NOTES

BLOOD PRESSURE READINGS

To the Editor:—*Present-day thinking on what constitutes arterial hypertension and when it becomes necessary to institute medical treatment seems in a rather confused state. How long is it necessary to record pressure readings under varying conditions before one may conclude what the basic pressure is? At what level, particularly diastolic, should the patient be advised that he has high blood pressure and treatment instituted?*

M.D., Arizona.

Answer.—There are so many variables involved in these two questions that a dogmatic answer would be misleading. In the first place, from the viewpoint of therapy, the habitual blood pressure during a typical, routine day is more significant than the basal level at rest or under sedation. The patient rarely spends more than a third of his time at rest. Secondly, the degree of variation on different occasions will differ greatly in different patients; in some four or five readings, observed in the morning, after lunch, in the evening, after a "tough time" on the job, or a row at home, the tension will fluctuate only slightly. In others the spread of variation may be great. Wide fluctuations are indicative of arteriolar spasticity and contraindicative of extensive arteriolar sclerosis and are therefore of considerable prognostic import. However, the extent of arteriolar spasticity versus arteriolar sclerosis may be determined in a very few minutes on the first examination and discovery of arterial hypertension by the application of the amyl nitrite test (*Arch. Int. Med.* 46:227 [Aug.] 1930; Geriatric Medicine, ed. 3, Philadelphia, J. B. Lippincott Company, 1954). This measures the fall in diastolic tension on the inhalation of amyl nitrite and is so prognostically significant that it should be included in the initial evaluation of all instances of hypertension. Other variables are the age of the patient (as a rule, the later in life the date of onset, the slower the progression of hypertensive disease); the known duration of the disorder (if the patient reports that a blood pressure of 180/110 mm. Hg was found 15 years previously and the level is nearly the same now, it is clear that the disorder is not progressing rapidly and there is no cause for alarm); and, last but not least, the probable etiological background (including prior nephritis, protracted anxiety, and plumbism).

If three or four readings made under variable circumstances vary no more than 20 mm. Hg systolic and 10 mm. Hg diastolic, the mean of the observations may be considered the habitual blood pressure of the patient. If the variations are extreme, as for example from 210/130 to 140/90 mm. Hg, it is clear that the situation is one of arteriolar spasticity, early in the course of the disease, and that the basal or habitual level is not significant. What is important is that this is evidence of vulnerability on the part of the arterioles to respond with excessive constriction upon stimulation; identification of the sources of the vasopressive stimuli (such as certain emotional situations or pheochromocytoma) and their correction becomes the primary therapeutic objective. The range of what is considered "normal" or "habitual" levels of arterial tension has been widened in recent years. An extensive study (Master, A. M.; Garfield, C. I., and Walters, M. B.: Normal Blood Pressure and Hypertension: New Definitions, Philadelphia, Lea & Febiger, 1952) leads to the conclusion that permissible normal systolic tensions cover a spreading, wider range as age advances. They state that at age 20 to 24 years the systolic range is from 100 to 130 mm. Hg, the diastolic from 60 to 85 mm. Hg, at age 40 these are systolic 105 to 150 mm. Hg, diastolic 65 to 94 mm. Hg; at age 50, systolic 110 to 160 mm. Hg, diastolic 70 to 100 mm. Hg; and at age 60, systolic 115 to 175 mm. Hg, diastolic 70 to 100 mm. Hg. These are statistically valid "normal" variations, but not necessarily levels of optimum health and/o longevity.

The second question, about when the patient should be informed that he has high blood pressure and treatment recommended, is also not amenable to dogmatic answer. This mus be individually decided, taking into consideration the personalit of the patient, the variability of the arterial tension, and th probable etiological picture. Persistent diastolic pressures ove 110 mm. Hg warrant attention; borderline situations are ofte best handled by an explanation that they are borderline, probably only potentially significant, with no implication of immed ate jeopardy, but that the time to arrest progression and eliminat so far as possible contributing causative factors is now rathe than 10 years from now when the disease may be fully established. The fuller, franker, clearer, and more comprehensiv the instruction of the patient into the nature, significance, an progressiveness of hypertension, the less likely is undesirab apprehension. Here as much as anywhere in medical practic the physician must be the teacher, the explainer, and the r assurer. Conservative therapy with continuing but not overdoi reassurance and study and correction of factors contributi to the hypertension are often sufficient to obtain excellent a lasting results. It is frequently expedient to emphasize that t findings merely reveal that the patient is vulnerable, reacti by a rise in blood pressure, to certain situations (such as e cessive fatigue, heavy responsibility, the pressure of deadlin and anger) just as a blond person is vulnerable to sunbu and that protection against sunburn when exposure is unavoi able is preferable to treatment after the injury is sustaine Lastly, it is important to keep in mind that the initial readi of the arterial tension, observed at the first visit of a new p tient, is almost invariably higher than subsequent observatio The patient is frightened, anxious as to what he or she w undergo, what will be found, and as yet not fully certain the physician. These initial readings, unless excessively hi must be discounted and no mention made of the hypertensi until its persistence is confirmed by subsequent observations.

STARVATION TREATMENT FOR DIABETES

To the Editor:—*Please tell me if the old Frederick Sterns a Allen starvation treatment for diabetes mellitus has merit a if so outline the treatment.*

K. E. Kerby, M.D., Nyssa, Ore.

Answer.—The question probably ıefers to the treatment i undernutrition as advocated by Frederick M. Allen in T Journal (**63**:939 [Sept. 12] 1914; and **66**:1525 [May 13] 191 in the *Boston Medical and Surgical Journal* (**172**:743, 191 and in the *American Journal of Medical Sciences* (**150**:480, 191 Undernutrition is acknowledged universally to have merit in t treatment of the obese diabetic patient and in most diabeti will often result in the urine becoming sugar free and may ma unnecessary the use of insulin. In the preinsulin days, it was great value, because it reduced the liability to acidosis a diabetic coma and encouraged the doctor to treat his patien intensively and to learn how much of the diet was utilize Undernutrition explained why certain bizarre diets or diets wi high fat and low carbohydrate and protein were of valu Actually they were undernutrition diets. Even today, utilizatio of the principle of undernutrition, combined with insulin, giv the speediest and best results in the inauguration of treatmen However, because of insulin, absolute fasting is practically neve necessary; indeed, even though an individual does omit food h does not actually fast but subsists on the carbohydrate, protei and fat stored in his own body. The original articles by Alle well deserve rereading by anyone deeply concerned in the treatment of diabetes. The following paragraph outlines his method of treatment.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

"If the patient is moderately emaciated, with a negative carbohydrate balance and acidosis, he is put to bed and receives no food whatever. Present experience indicates that even in severe cases ketonuria may by this method be made to disappear entirely. Several repetitions of the foregoing routine may be necessary for this purpose. All food contains danger, tending toward either glycosuria or ketonuria. The carbohydrate of the diet is seldom reduced below 50 gm. and is preferably kept higher. If carbohydrate must be kept low, the total diet is kept low. The diet is so chosen that glycosuria not ketonuria, is the signal of overstrain. If there has been no glycosuria, a slight addition to the diet is made after each fast-day. Each day's diet is calculated exactly, and the nitrogen-balance is watched. The attempt to increase weight should be the last rather than the first step in treatment. It is attempted to keep the metabolism at the lowest safe level until the patient is taking from 100 to 150 gm. of carbohydrate (mostly as green vegetables) daily, with fast-days interposed often enough to prevent any trace of glycosuria from appearing. Then protein is cautiously added, always being kept rather low; and in favorable cases the weight and well-being may finally improve under gradual additions of fat. The radical procedure here described is that used for the most severe cases. In milder cases the treatment may be correspondingly milder. Primary loss of weight is intentional."

Joslin's statistics show the average duration of life of diabetics who died between 1897 and May 31, 1914, was 4.9 years but in the subsequent eight-year period, when the treatment was influenced by Allen's undernutrition ideas ending with the discovery of insulin, it rose to 6.1 years, and the mortality from diabetic coma dropped from 63.8% to 41.5%. Joslin's method (Treatment of Diabetes Mellitus, Philadelphia, Lea & Febiger, p. 243, 1916) for the utilization of undernutrition was as follows:

"*Preparation for Fasting:* In very severe, long-standing, complicated, obese and elderly cases, as well as in all cases with acidosis without otherwise changing habits or diet, omit fat, after two days omit the protein, and then halve the carbohydrates daily until the patient is taking only 10 grams; then fast. In other cases begin fasting at once.

"*Fasting:* Fast four days, unless sugar-free earlier. Allow water freely; tea, coffee and clear meat broths as desired."

By the above plan few cases needed to fast. As soon as the urine was sugar free the diet was gradually increased. In those bygone days without insulin, undernutrition really revolutionized treatment in diabetes and much further progress undoubtedly would have been made in the next decade had insulin not been discovered. Of course, insulin was so efficient that it almost outmoded all the good ideas in the diets painstakingly learned during the preceding century.

SACCHARIN AND THROMBOCYTOPENIC PURPURA

To the Editor:—*A 73-year-old practicing physician was found one year ago to have a thrombocytopenic purpura, with a platelet count that varies from 18,000 to 45,000 per cubic millimeter. He has a normal red blood cell count, normal hemoglobin level, and a normal total white blood cell count but with a moderate relative leukopenia. The spleen is not enlarged, and sternal puncture gave equivocal findings. He shows moderate ecchymosis following slight trauma but has not had mucous membrane hemorrhages. After gastrectomy for duodenal ulcer five and a half years ago, he was given large doses of penicillin without untoward reaction. For three years before discovery of the condition, he used saccharin freely in coffee and cereals in amounts of 1 to 4 grains (0.065 to 0.25 gm.) daily. Is there any evidence to support the suspicion of the saccharin as a causative factor in this condition?*

M.D., California.

Answer.—This question was reviewed both by a consultant with extensive experience in examining patients who use saccharin daily and by another consultant who is interested in hematology and has seen a large number of patients with thrombocytopenic purpura. Neither consultant thinks that the saccharin has had anything to do with this condition.

DIABETES INSIPIDUS

To the Editor:—*A 4½-year-old child has diabetes insipidus, bone destruction on both sides of the mandible, a bony defect in the right mastoid, and a small, slightly osteoporotic area in the right frontal bone. She has anemia (hemoglobin level 8.7 gm. per 100 cc., and red blood cell count 3,240,000 per cubic millimeter). The clinical diagnosis of histiocytosis, Hand-Schüller-Christian type, was confirmed by biopsy. The diabetes insipidus is under control with powdered posterior pituitary extract. Contemplated roentgen therapy is to be given by a qualified radiologist. What is the potential danger of radiation damage to the brain? What other therapeutic measures are available for histiocytosis? Because of the granulomatous nature of lesions of this type, antibiotic treatment has been suggested besides x-radiation. What antibiotic should be used? Heinz C. Meyer, M.D., Konnarock, Va.*

Answer.—The best method of handling this patient would be with radiation therapy. Each area of known involvement should be treated at the outset. The dosage necessary to produce regression of the lesions is low, in the neighborhood of 300 r. After the first course of treatment, the patient should be rechecked at frequent intervals (about three months) and further treatment given to any new areas that may appear or to areas that are not improving. With low total dosage of x-rays, there should be little chance of brain damage from x-rays if they are administered by an experienced radiologist. Antibiotic therapy cannot be expected to affect this disease. The articles listed below outline methods of therapy and results that may be achieved.

HOSTILE CERVICAL MUCUS

To the Editor:—*I have encountered a second infertile couple who demonstrated an abnormality that I have not seen discussed. The postcoital examination shows normal cervical mucus with no spermatozoa while the semen in the vagina shows large numbers of apparently normal and active spermatozoa. Although the spermatozoa lash heads and tails about vigorously, not one was seen to progress any distance at all on the slide. Both women have been demonstrated to be normal by all available tests. The first husband was referred to a urologist who gave a normal report and mentioned an excellent semen analysis with 95% motility initially and 50% after 24 hours. I have tried washing the spermatozoa obtained from the vagina and titrating with alkali and acid without causing any progress to be made, even though the spermatozoa continued trying through a wide pH range. Intrauterine instillation of the husband's spermatozoa has been tried several times without avail. What might be done to help these patients?*

Thomas V. Judge, M.D., Orange, N. J.

Answer.—Hostile cervical mucus is a frequent cause of infertility. It is usually due to increased viscosity and is often produced by infection. It may be associated with a high endocervicitis that is amenable to antibiotic therapy or cautery, but the viscosity is more frequently due to lack of response to estrogenic stimulation just prior to ovulation. Theoretically, it is possible to bypass this obstruction to the penetration of spermatozoa by means of intrauterine insemination. However, this procedure is both technically difficult and potentially dangerous. Several months' trial with estrogenic hormones is indicated before any other form of therapy is attempted. Diethylstilbestrol therapy, 0.1 mg. daily during the first two weeks of the menstrual cycle, should be given. If this small dose does not produce the desired effect, it may be doubled, with the understanding that the latter dose may delay ovulation. Estrogens may also be administered by hypodermic injection: 5 mg. of estradiol benzoate between the 5th and 10th day of the cycle has been shown to be effective in thinning out the cervical mucus. A great deal has been published on the subject of hostile cervical mucus, especially in the *Journal of Fertility and Sterility.*

TREATMENT OF PARATHYROID TETANY

To the Editor:—*A 28-year-old woman, gravida 1, had a subtotal thyroidectomy in February, 1954, for a diffuse toxic goiter. A pathologist examined the specimen and found no evidence of parathyroid tissue. Nevertheless, the patient developed tetanic symptoms and a low blood calcium level (6.5 mg. per 100 cc.). She was treated with intravenously administered calcium and parathormone for several days with good response and then was gradually given oral doses of calcium lactate 20 grains (1.3 gm.) four times a day and 2 cc. of dihydrotachysterol every other day. After a month, the dosage of the dihydrotachysterol was gradually reduced to 1 cc., and after another month to once a week, but the dosage of calcium lactate was kept the same. Pregnancy intervened, and she carried a normal female infant to full term and had an uneventful delivery with saddle block anesthesia. She was maintained on the 20 grains (1.3 gm.) of calcium lactate and the weekly dose of 1 cc. of dihydrotachysterol throughout the pregnancy and shortly afterward. A blood calcium level taken post partum on the fourth day was 8.6 mg. per 100 cc. Lactation was promptly suppressed with stilbestrol. She went home symptom free. The dihydrotachysterol is now being given in doses of 1 cc. every three weeks, but any effort to cut the calcium lactate below 15 grains (1 gm.) three times a day results in numbness and tingling of the hands and feet. Now she is almost three months post partum, and she has begun to develop some joint pains, difficulty in straightening up from a sitting position, and some stiffness in the knees. I would appreciate suggestions.*

M.D., Michigan.

Answer.—It is common practice to treat parathyroid tetany by the method outlined in the case report. Dihydrotachysterol or vitamin D frequently is not required if the patient has received adequate amounts of calcium. It is considered good practice to give sufficient calcium to maintain the serum calcium level between 9 and 11 mg. per 100 cc., if possible. The effectiveness of treatment should be judged on the basis of control of blood calcium level—rather than on control of symptoms, because some patients fail to notice or will ignore a few mild symptoms or possibly have no symptoms most of the time despite abnormally low serum calcium levels. If the serum calcium level is not maintained within normal range, trophic disorders are more likely to develop. Changes such as those that occur in the nails and hair are reversible; development of cataract is not reversible and must be prevented. The following therapy is recommended. Calcium lactate powder, a level to slightly rounded teaspoonful, should be given three times a day. The powder can be easily prepared for effective administration by dissolving it in hot or boiling water, 1 teaspoonful to each glass of water. It usually can be prepared in the evening and then refrigerated until it is needed the following day. If the calcium lactate powder is not sufficient to raise the serum calcium level to normal range, dihydrotachysterol or vitamin D may be added in a dosage sufficient to do so. Vitamin D is thoroughly efficient; a dose from 50,000 to 150,000 units or more daily may be necessary. With this therapy, there is no evidence that metastatic calcification will occur, provided hypercalcemia does not exist. Hypercalcemia can be prevented by adjusting the treatment according to the serum calcium and phosphorus levels estimated at intervals of a few weeks or months, or if the patient watches for hypercalciuria by means of the Sulkowitch test.

MASS IMMUNIZATION

To the Editor:—*Are there any contraindications in giving tetanus toxoid and typhoid-paratyphoid in the same injection for mass immunization?*

Duane F. Hartshorn, M.D., Fort Collins, Colo.

Answer.—For effective immunizations there should be no objection to combining tetanus toxoid and typhoid-paratyphoid in the same injection. However there is always the possibility of having a rather severe reaction from typhoid-paratyphoid vaccine that someone might attribute to the mixture of antigens. A more important matter to consider for mass immunization is the requirement that a separate syringe as well as a different needle be used for each person. The danger of transmitting infectious hepatitis when there are multiple injections from the same syringe should not be overlooked nor ignored.

DRAINAGE FROM AMPUTATION STUMP

To the Editor:—*A patient had a midthigh amputation six months ago because of diabetic gangrene of the left leg. Diabetes is adequately controlled by diet and 20 to 25 units of Lente insulin daily. However, since her amputation there has been some mucopurulent drainage from three small places on the stump scar line that has not responded to treatment with broad spectrum antibiotics or penicillin. Culture from the drainage sites revealed Micrococcus (Staphylococcus) albus as the predominating organism. What suggestions have you to offer to stop the persistent drainage?*

James P. Landay, M.D., Duquesne, Pa.

Answer.—Persistent drainage in a stump following amputation for gangrene is likely to result from devitalized tissue left at the time of surgery. It is difficult to recognize muscle with a marginal blood supply. The edema following the surgical trauma is sufficient to impair the vitality of such tissue. Another source of drainage is the large pedicle distal to ligatures. The custom of stripping the periosteum from the femur prior to transection may devitalize bone. Bone chips from the saw may form the nidus. Drainage from any surgical wound may persist due to a foreign body left in the wound. Excessive numbers of large sutures, or even a sponge, may be suspected. Drainage occurs occasionally from a low-grade micrococcic infection of subcutaneous fat. Injection of the sinus with a contrast medium such as lipiodol may yield a clue as to the site of the difficulty. Gentle exploration of the sinus permits identification and removal of the cause with resultant healing.

AUSCULTATORY GAP

To the Editor:—*A man, aged 56, is physically essentially normal except for hypertension from 210 to 160 mm. Hg systolic and 110 to 90 mm. Hg diastolic. There is a complete loss of sound after a drop of 30 mm., recurring faintly at 40 mm. drop, and becoming normally audible again to the diastolic. I cannot rationalize this finding. Such applies only to right arm and in all positions.*

J. J. Blue, M.D., Cedarville, Mich.

Answer.—This is the phenomenon known as the auscultatory gap. If the cuffs are inflated rapidly so as to avoid venous congestion distal to the cuff, no gap occurs when the cuff is deflated. When inflation is done gradually, the gap is observed on deflation. Prolonged partial occlusion of the veins of the arm during the inflation of the cuff affects both arterial and venous pressure distal to the cuff and the effect on the arterial pressure seems to be the determining factor in eliciting the auscultatory gap. For details see C. Ragan and J. Bordley III (Measurements of Blood Pressure *Bull. Johns Hopkins Hosp.* 69:504, 1941).

MALE CLIMACTERIC

To the Editor:—*Is there such a condition as the male climacteric in a male aged 52 years that comes on suddenly with hot flashes, occasional slight temperature, nervousness, mental lassitude, burning of feet, and impotency? The 17-ketosteroids in a 24 hour urine specimen are above normal, and the remainder of the physical examination is normal. Large or small doses of androgens are of no help. Both androgens and estrogens are of no help in controlling the hot flashes and mental condition. Nothing improves the potency. Are males permanently impotent after the climacteric?*

M.D., Michigan.

Answer.—The onset of climacteric in the male is not sudden. A skull x-ray with particular reference to the sella turcica is indicated in all males who have unexplained loss of potentia. Testosterone propionate, intramuscularly, three times weekly for four to six weeks will restore lost potentia that is organic in origin but not psychic. Males are not permanently impotent after the climacteric. If no organic disease (systemic or local) is present, further psychiatric evaluation and treatment is indicated.

SURGICAL CORRECTION OF TETRALOGY OF FALLOT

RESULTS IN FIRST ONE HUNDRED CASES SIX TO EIGHT YEARS AFTER OPERATION

Willis J. Potts, M.D., Stanley Gibson, M.D., Chicago
Edward Berman, M.D., Indianapolis, Harvey White, M.D.
and
Robert A. Miller, M.D., Chicago

On Friday, Sept. 13, 1946, the first aortic-pulmonary anastomosis was performed at the Children's Memorial Hospital for relief of cyanosis due to tetralogy of Fallot.[1] This operation varies from that originally devised by Blalock and Taussig[2] in 1945 in that blood is shunted into the pulmonary circulation directly from the aorta instead of by means of the subclavian artery. The principle of each operation is the same. "What has happened to the children who have had a shunt operation for Fallot's tetralogy?" is frequently asked. To obtain a tentative answer to this question we have made follow-up studies of the first 100 consecutive patients operated upon at the Children's Memorial Hospital. We have included all patients with a diagnosis of tetralogy of Fallot upon whom some form of anastomosis could be performed. We have excluded those who, because of tiny or absent pulmonary arteries, had exploratory operations only. Obviously, it is impossible at this time even to suggest actuarial statistics, since only six to eight years have elapsed between the operations and the study. Immediate and late mortality figures thus far are specific; evaluation of the condition of those who have survived until now is a matter of opinion based upon our clinical and laboratory examinations.

These patients came from many states and Canada, the British Isles, Europe, and Israel. By good fortune and some persistence, we have been able to follow every living patient and to obtain reports on the causes of death of those who died after leaving the hospital. Our objective in this study has been to evaluate the results of operations primarily from clinical and roentgenologic examinations. Electrocardiographic studies and simple laboratory examinations were routinely made, but complicated precedures, such as cardiac catheterization and angiocardiograms, were not part of the follow-up program.

PREOPERATIVE EVALUATION OF PATIENTS

When cardiac surgery for heart disease with cyanosis was started in 1945 and 1946, there were many children in rather desperate condition who had somehow remained alive. This group and a considerable number of smaller children for whom aortic-pulmonary anastomosis was especially devised comprised the first 100 cases.

Age.—In this series 35 patients were between 4 and 36 months of age and 65 were between 3 and 16 years at the time of operation. Age is an especially important factor in mortality and clinical results. The child who in the first year of life becomes severely cyanosed and has attacks of dyspnea and unconsciousness obviously has a severe degree of stenosis. Such children die at an early age without surgery, and those who survive operation are not apt to have as good results as those children whose early symptoms are less severe. It has always been our policy to refuse operation to no child regardless of age or condition, provided a diagnosis of diminished blood flow to the lungs can be made. Operation is delayed in smaller children if their clinical condition indicates waiting is safe.

Blood Findings.—The average red blood cell count before operation was 7,100,000 per cubic millimeter; the highest was 11,000,000. The average hemoglobin reading was 18.5 gm. per 100 cc. Both dropped precipitously after successful operation—the red blood cell count to approximately 5,000,000 per cubic millimeter and the hemoglobin level to approximately 15 gm. per 100 cc., where they remained in those patients whose cyanosis was largely relieved. A slow rise to previous levels was observed in four patients who required second operations.

Preoperative Risks.—Evaluation of the anesthetic risk was made by the anesthesiologist, Dr. William O.

From the Children's Memorial Hospital.

[1] Potts, W. J.; Smith, S., and Gibson, S.: Anastomosis of the Aorta to a Pulmonary Artery: Certain Types in Congenital Heart Disease, J. A. M. A. 132: 627-631 (Nov. 16) 1946.

[2] Blalock, A., and Taussig, H. B.: The Surgical Treatment of Malformations of the Heart in Which There Is Pulmonary Stenosis or Pulmonary Atresia, J. A. M. A. 128: 189-202 (May 19) 1945.

McQuiston. Because of the figures that follow, one might suppose that the anesthesiologist was a bit pessimistic, or, with a view towards self-protection, made a rather dismal appraisal of each patient. In support of his analysis, one must bear in mind that, in the early days of surgery for tetralogy of Fallot, the percentage of markedly cyanosed children was high. In reviewing the cases we are inclined to agree with his evaluation. Preoperatively, 40 patients were classed fair to good risks and 60 as poor to bad. If one classifies a normal child who is to have repair of an inguinal hernia as an excellent anesthetic risk and a child with bronchiectasis who is to have a lobectomy as a good risk, it seems only proper to place the child with severe cyanosis with low respiratory reserve in a lower classification.

OPERATION

An aortic-pulmonary anastomosis was performed in 99 patients and a subclavian pulmonary anastomosis in one. The aorta arched to the left in 81 patients and to the right in 19. As a matter of fact, the subclavian pulmonary anastomosis performed on the 99th patient closed (see case 4 below). Actually, therefore, this becomes a study of the late results of aortic-pulmonary anastomosis. At first we persisted in doing aortic-pulmonary anastomoses on all patients with tetralogy of Fallot regardless of whether the aortic arch curved right or left. It then became and still is our policy to enter the chest on the left side in all patients above one year of age. If the descending aorta is on the left side, an aortic-pulmonary anastomosis is preferred; if the arch curves to the right, the innominate artery will be on the left, and a subclavian-pulmonary anastomosis on the left side is performed, because it is far simpler technically than an aortic-pulmonary anastomosis on the right side. We now perform aortic-pulmonary anastomoses on the right side only in infants whose condition is such that immediate operation is imperative.

The size of the anastomotic channel in an aortic-pulmonary anastomosis is easily controllable. In our early cases, incisions in the aorta and the pulmonary artery preparatory to anastomosis were made 0.31 in. (8 mm.) long, giving an anastomotic channel 5 mm. in diameter. Marked enlargement of the heart in one patient prompted us to shorten the incision to 0.25 in. (6.3 mm.). Such incisions produce an anastomotic channel 4 mm. in diameter. We still continue to make the incisions 6.3 mm. long in all children except infants, in whom they are made 5 mm. long because we anticipated considerable growth of the anastomotic channel.[3] In each instance the length of the incision is carefully measured with a caliper. That more children in the first few cases in whom incisions in the vessels preparatory to anastomosis were made 8 mm. long have not developed excessive enlargement of the heart is most likely due to the fact that suturing then was rather poorly done. Anxiety about bleeding and inexperience prompted us to sew rather snugly, and, in so doing, we undoubtedly—and fortunately—constricted the anastomotic channel somewhat. All anastomoses were made with 00000 Deknatel silk and still are in most cases. However, in infants in whom the vessels are small and in older children who are to have a subclavian-pulmonary anastomosis and whose subclavian arteries are small, 000000 silk is used to lessen the amount of foreign material in the apposed vessels.

Four patients required second operations to relieve recurrent cyanosis.

CASE 1.—A patient, aged 8, had upon admission in 1948 a red blood cell count of 7,300,000 per cubic millimeter and a hemoglobin level of 23 gm. per 100 cc. An aortic-pulmonary anastomosis was performed on the right side under difficulties. Severe hemothorax and pneumothorax complicated the postoperative period. Improvement was minimal and temporary. Two years later a subclavian-pulmonary anastomosis on the left side was followed by a good result.

CASE 2.—A patient, aged 6, a good risk, had an aortic-pulmonary anastomosis on the left side in 1948. Fragmentation of the aorta occurred during the anastomosis. An extra stitch was required to close the rent. When the clamps were removed, there was a barely palpable thrill. Postoperative improvement was questionable. Symptoms recurred, and a subclavian-pulmonary anastomosis was done in California in 1951. The final result was fair.

CASE 3.—A patient, aged 3 years, a fair risk, had an aortic-pulmonary anastomosis on the right side in 1947. For three months the child did well, but then the diastolic phase of the murmur disappeared and cyanosis recurred. In 1949 a subclavian-pulmonary anastomosis was performed on the left side. Immediate improvement was again followed by disappearance of the diastolic murmur and recurrence of cyanosis. At the time of this study, the boy had not improved. The mother made an astute observation. Marked keloid formation of the skin followed each operation, and on the boy's arm a hard, large keloid persisted as a sequel to vaccination during early childhood. The mother wondered whether this tendency toward keloid formation might have caused both anastomoses to close.

CASE 4.—A 4-month-old child who was admitted in 1948 was rather severely handicapped with tetralogy of Fallot and a left aortic arch. The chest was opened on the left, but an aortic-pulmonary anastomosis was impossible because the pulmonary artery was very short. The subclavian artery was sutured to the side of the pulmonary artery. Because the subclavian artery was unusually large, it was constricted slightly by drawing the anastomotic suture more snugly than usual. We believe from later experience that constriction of the subclavian artery at the site of its anastomosis to the pulmonary artery is apt to lead to thrombosis, probably due to excessive eddies in the blood stream. The child was improved, but cyanosis slowly recurred and the diastolic phase of the murmur disappeared. In 1953 a subclavian-pulmonary anastomosis was performed on the right side with a good result.

To the best of our knowledge, the second case cited above is the only one in which the anastomotic channel closed following aortic-pulmonary anastomosis on the left side in a patient who survived operation for tetralogy of Fallot. However, the anastomotic channel closed in two instances of aortic-pulmonary anastomosis performed on the right side.

MORTALITY

In the first 100 patients operated upon for tetralogy of Fallot, there were nine hospital deaths. In 35 children from 4 to 36 months of age, there were six deaths, or a mortality of 17%. In 65 children between 3 and 16 years, inclusive, there were three deaths, or a mortality of 4.6%. The causes of death were as follows: anoxia, three; tension pneumothorax, one; septicemia and intracranial hemorrhage, one; cerebral hemorrhage, one; subacute bacterial endarteritis and septicemia, one; thrombosis at site of anastomosis and saddle embolus occluding the aorta, one; multiple anomalies of the heart and great vessels, one. The mortality in approximately 200 patients from 2 weeks to 3 years of age operated upon to date is 15.3%, and in about the same number of children from 3 to 16 years of age, the mortality is now 3.6%. It is well recognized that the mortality in small children will be high, as they are operated upon at this age only because they cannot otherwise survive. Discussion of mortality statistics following operations for tetralogy of Fallot is futile, unless the ages of the patients are taken into consideration.

---

[3] Potts, W. J., and Riker, W. L.: Study of Growth of Aortic-Pulmonary Anastomoses, Surg., Gynec. & Obst. 94:358-360 (March) 1952.

Five patients died after leaving the hospital. All showed varying degrees of improvement but died of the causes described below.

CASE 5.—A patient, aged 2½ years and weighing 23 lb. (10 kg.), who had been deeply cyanosed since birth and required almost constant oxygen, had an aortic-pulmonary anastomosis on the right side in 1947. Her recovery was uneventful and dramatic. Following chickenpox, measles, and two attacks of pneumonia and atelectasis, she died of chronic pulmonary infection in October, 1950. Her color had remained good, and the continuous murmur had persisted.

CASE 6.—A patient, aged 1½ years, was a puny, helpless child who had weighed 15 lb. (6,804 gm.) and had a red blood cell count of only 5,000,000 per cubic millimeter. An aortic-pulmonary anastomosis was done in 1947. The postoperative course was complicated by pneumonia. On follow-up visits one and two years after surgery, a continuous murmur was heard. The child was improved but never robust. The heart was 50% enlarged two years after surgery. The family physician reported that the child died of pneumonia at home shortly after the last visit.

	No. or %
Group 1: Good	68
Group 2: Fair	16
Group 3: Poor	1
Group 4: Unchanged	1
Group 5: Improved, but died later	6
Group 6: Hospital mortality	9
Total	100

CASE 7.—A 7-year-old patient, a good risk, who was able to walk about one-half block before squatting and had a red blood cell count of 6,500,000 per cubic millimeter, had an aortic-pulmonary anastomosis in 1947. Following operation he was well and very active. At the one year check-up examination, there was a continuous murmur, and the heart showed 10% enlargement. He died at home of acute rheumatic fever one year later, according to his family physician.

CASE 8.—A patient, aged 2½ years, with a red blood cell count of 8,300,000 per cubic millimeter, was admitted on Oct. 18, 1947. For three months prior to admission she had had unexplained intermittent fever diagnosed as subacute bacterial endocarditis, although repeated cultures were negative. After an afebrile period, an aortic-pulmonary anastomosis was performed Oct. 21, 1947, and was followed by uneventful recovery and marked improvement until Feb. 19, 1948, when she was readmitted with high fever and findings suggestive of a brain abscess on the right side. She died seven days later and, at postmortem examination, a large brain abscess was found in the right cerebral hemisphere. In retrospect, we believe that the child had an unrecognized brain abscess before operation and that it later flared up with a fatal result. The aortic-pulmonary anastomotic channel was clear and measured 4.5 mm. in diameter.

CASE 9.—A patient, aged 7 months, weighing 12 lb. (5.4 kg.), who had been cyanosed since birth, was admitted with a diagnosis of tetralogy of Fallot. An aortic-pulmonary anastomosis was performed March 24, 1948, and, because the aorta and pulmonary artery were very small, the anastomotic channel was made only 3 mm. in diameter. The child did well after operation. At the six month check-up examination there was a continuous murmur and the heart showed only 10% enlargement; however, about a year later she began having "heart attacks" and died at her home two years after operation, presumably of heart failure.

CLINICAL EVALUATION

Our prime interest in this study was to determine the clinical results in those 86 patients alive six to eight years following aortic-pulmonary anastomosis for tetralogy of Fallot. Follow-up studies included clinical evaluation of every patient. Many patients have been seen every year since operation. Patients living in foreign countries and in states far removed from Chicago were evaluated by reports from parents and physicians, who cooperated enthusiastically. Repeated róentgenograms of the heart were made of patients living in and about Chicago and were compared with previous films. Electrocardiograms likewise were part of the checkup routine. The large majority of patients were seen and evaluated personally by at least five peoeple.

It is obviously impossible to fashion an accurate measuring device for evaluation when dealing with such intangibles as parental pride, comparison of physical condition "before and after" operation, and the patient's own desire to be considered normal and therefore free from restraints. It was decided to place in group 1 children who show little or no visible cyanosis when at rest and slight cyanosis after exercise; who are able to attend public school, play, ride bicycles; and who, in general, do what other children of their age do, with the exception of violent exercise. (Recognizing that no child's heart is normal after any operation for tetralogy of Fallot even though all visible signs of cyanosis have disappeared, it has routinely been our advice that all competitive athletics be avoided after operation. Not all have heeded our advice.)

In group 1 were placed 68 children. It was interesting to observe that residents and fellows in cardiology were inclined to place children in a higher category of improvement than those who had been active in their treatment. All of these children had the characteristic continuous murmur of a functioning artificial ductus. One boy, aged 11, operated upon in 1947, who was deeply cyanosed before operation, was asked before leaving the hospital what he intended to do when he returned home. His unhesitating reply was "Beat up the boys who used to call me 'blue lips.' " When he returned for check-up examination seven years later he reported, "Mission accomplished." Furthermore, he now caddies during the summer months and boasts that on the hilly course he can caddy double and keep up with the other boys. The heart is truly "tough." Included in this group is a boy now 17 years of age, operated upon when he was 9, who, clinically, has an excellent result. His x-ray film, however, shows an aneurysmal dilatation of the left pulmonary artery. We consider his future uncertain. Another child was well for six years after operation and has recently recovered from what was interpreted by the family physician as bacterial endocarditis. To our knowledge, this is the only case of late bacterial invasion of the vessels in this series of living patients. In general, these children and young adults live more or less normal lives; they walk to school, climb stairs, and chafe under the restrictions placed upon them by their parents. Many, however, will admit under pointed questioning that they tire more easily than their schoolmates.

In group 2 were placed those children who are moderately handicapped. They tire easily on moderate exertion. Some have persistent mild cyanosis when at rest, but all become cyanosed upon exertion or when fatigued. They are excused from all gymnasium work. In this group were placed 16 children. All show moderate to marked improvement over their condition before surgery. All but one have the characteristic continuous murmur. In group 3, the severely handicapped, is one patient; a 13-year-old girl who was operated upon in January, 1947. Because she had been bedridden for two years before surgery, a large anastomosis, 6 mm. in diameter, was made. She was promptly relieved of all cyanosis. The following summer she went on a vacation to Yellowstone Park, where she was allowed to run and climb as she wished. At the first check-up examination nine months after surgery, her heart was tremendously enlarged, and before the end of the year she went into heart failure. She has been in heart failure a number of times since then and goes to a school for the handicapped. Her heart remained the same size for seven years. During the past year her heart has decreased from 125% to 60% enlargement. She has developed an aneurysm of the left pulmonary artery, and, presumably because of this, the diastolic phase of the murmur disappeared. She continues to be free from cyanosis but, obviously, has a poor prognosis. Why her heart has decreased in size we do not know. In group 4, the unimproved, is one patient (case 3) who had two operations. Each operation was followed by only temporary improvement. The remaining 14 patients have been discussed in the section on mortality.

TABLE 2.—*Cardiac Enlargement Six to Eight Years After Aortic-Pulmonary Anastomosis*

No. of Patients	%*	Clinical Estimate
13	0-15	Little or none
15	15-30	Slight
14	30-50	Moderate
6	50-75	Large
3	75-100	Very large

* Measured according to Meyer's[4] method.

ROENTGENOGRAPHIC FINDINGS

Although roentgenograms were obtained after the operation in the majority of patients, some of the films were inadequate for comparative studies, and occasionally we could obtain reports only without films. Measurements of heart size were made according to the method of Meyer.[4] His method is based on the work of Hodges, Adams, and Gordon,[5] who correlated the height and weight of a child with the size of the heart. Meyer simply measures the long and short diameter of the heart, correlates these with height and weight in children, and expresses degrees of enlargement in percentages. This method of calculating percentages of cardiac enlargement is undoubtedly more accurate than comparisons of the cardiothoracic ratios. All his studies, however, were made on children over 3 years of age. Recognizing that in growing children, especially in smaller children under 3 years of age, comparison of heart size from year to year is not mathematically infallible, we have interpreted to the best of our ability the roentgen studies of heart size as listed in the table. In 51 of the 86 children who survived for six to eight years following surgery, adequate data was available for fairly accurate measurements. It will be noted in table 2 that we have listed percentages of enlargement as calculated by one of us (H. W.), along with common descriptive terms used by clinicians.

It is a curious fact that, although these children all had approximately the same operations, there is such a discrepancy in the degree of cardiac enlargement following surgery. We can only assume that the size of the anastomoses varied somewhat in spite of careful measurement with calipers of the incision in the vessels or that the anastomosis increased in size more in some patients than in others. Variation in the uncorrected pathology inside the heart may also be a factor.

When comparing clinical and roentgenographic findings, it is at once apparent that we have placed only one child in group 3, the severely handicapped, and yet report a number of children whose hearts are markedly enlarged. Roentgenographic and clinical interpretations were made separately and then compared. Even after seeing the large hearts as shown on the films we could not place these children anywhere but in group 1 because, clinically, they are well and have at no time shown signs of cardiac embarrassment. In fact, one boy now a sophomore in high school has actually, though unwisely, gone out for track work. None show cyanosis except with vigorous exercise. These hearts became large rather promptly after operation and have remained approximately the same size for six to eight years. We debated long into which classification we should place those children who have very large hearts and considered that they belong in group 1 so long as they are clinically well and active. A few children with typical postoperative continuous murmurs and little enlargement of their hearts, nevertheless, have only fair clinical results and were placed in group 2. Heart size after operations for tetralogy of Fallot is undoubtedly an important factor in ultimate prognosis but is not a guide in early results, that is, for six to eight years. What the heart muscle unhampered by disease of its vessels can do is constantly astounding.

ELECTROCARDIOGRAPHIC FINDINGS

Of 86 patients living at the time of this study, 50 had satisfactory preoperative and postoperative multiple lead electrocardiograms that were adequate for comparable studies. Interpretation of electrocardiographic tracings in children taken over a period of six to eight years must be made with the understanding that electrocardiograms constantly change with growth, especially during the first five years of life. Twenty-eight patients (56%) had changes in the electrocardiogram that were

thought to be related to the operative procedure. Changes were limited to the P waves in 14. Within six months to one year after surgery the peaked, prominent "P congenitale" in leads 2 and 3 became much smaller or assumed normal contour. Changes in contour of QRS, S-T segment, or T wave appeared in 14. In six of these the R wave became smaller over the right chest leads, the QRS in lead 1 changed from inverted to diphasic or small and upright and the S wave over the chest leads became smaller. That is, electrocardiographic evidence of strain of the right side of the heart decreased over the years in these six patients without evidence of left ventricular hypertrophy.

Definite evidence of combined heart strain appeared after operation in six children. Evidence of a tall RR′ pattern or delayed intrinsicoid deflection in the right chest leads, with a tall R wave, depressed S-T segment, and low amplitude, flat or inverted T waves over the left side of the chest were considered evidence of combined heart strain or biventricular hypertrophy. It is worthy of note that only two of the children who have marked postoperative enlargement of the heart are in this group of six who show electrocardiographic evidence of combined heart strain. One patient developed progressive lengthening of the PR interval from 0.10 to 0.28 second over a period of five years. Significant but nonspecific QRS changes in the limb leads appeared in one patient. The general impression derived from this study was that, aside from six patients who developed a pattern of combined heart strain, the electrocardiographic changes over the years after aortic-pulmonary anastomosis revealed few significant changes.

COMMENT

In this interim report of the first 100 consecutive patients operated upon at the Children's Memorial Hospital for tetralogy of Fallot, we have tried to give a fair appraisal of results but recognize, first, that our collection of data left something to be desired. Although the large majority of patients were seen and examined, we had to be satisfied with telephone conversations with or questionnaires from patients for whom it was not possible to travel long distances to Chicago. It is well recognized that parents quite naturally shade their opinions in favor of good reports concerning their children. Second, we recognize that when dealing with an intangible factor such as clinical evaluation of a patient—in spite of the intended stern attitude of impersonal appraisal—the examiner is bound to be influenced favorably by the swaggering, enthusiastic boy and the bright-eyed girl in a crisply starched dress. Allowing for our prejudices, we believe we have given a rather fair analysis of the patients who survived following operation for tetralogy of Fallot.

SUMMARY

In a follow-up study of 100 children operated on for tetralogy of Fallot, results six to eight years after operation were good in 68% and fair in 16% of cases. One patient was classified as having a poor result and one as unchanged. Fourteen patients have died; five of these improved after operation but died later. The hospital mortality was 9%.

LIVER FUNCTION AND HEPATIC COMPLICATIONS IN PATIENTS RECEIVING CHLORPROMAZINE

Irvin M. Cohen, M.D.
and
John D. Archer, M.D., Galveston, Texas

The use of chlorpromazine [Thorazine, 10-(γ-dimethylaminopropyl)-2-chlorophenothiazine hydrochloride] is occasionally complicated by the development of jaundice. In our series of over 800 patients treated with this drug, 5 such cases have occurred. Results of laboratory studies in these instances have consistently indicated an obstructive process within the biliary system. The complication has proved to be benign, the ensuing clinical courses being characterized by rapid resolution of symptoms and uneventful recovery. Though this side-reaction occurred only rarely and was apparently confined to the bile passages, we believed that the possibility of damage to the liver cells demanded further investigation. Of particular concern to us was the question of whether patients receiving the drug over relatively long periods of time sustained subclinical liver damage. The presence of the phenothiazine nucleus in chlorpromazine further suggested the need for this determination, since phenothiazine itself, in sufficiently high dosage, has been reported to produce liver disease.[1]

The aim of the study, therefore, was to ascertain (1) whether chlorpromazine represented a highly specific hepatotoxin and, if so, the site of damage, or (2) whether liver involvement was simply a random effect that could be expected to occur in a certain number of patients hypersensitive to the drug. Though definitive conclusions must await further study, the results that follow represent impressions derived from a preliminary investigation of these questions.

MATERIAL

The study included a total of 89 patients, all of whom were being treated for psychiatric illnesses of various clinical types. In no case was there a history of liver dis-

ease, and physical examinations had revealed no findings of contributory significance. For purposes of this report the patients are divided into three groups. Group 1 consists of five cases in which clinically evident jaundice developed. Table 1 shows age and sex distribution, diagnosis, the presence or absence of allergic history, and other complications that developed during the course of therapy. Table 2 shows duration of administration of chlorpromazine prior to appearance of icterus; minimum, maximum, and average doses that had been given; and route of administration. Group 2 consists of 14 patients who were subjected to an extensive battery of liver function studies prior to and during the administration of a generally constant dose of chlorpromazine for periods of time varying from two to six weeks. Group 3 consists of 70 cases in which less extensive liver function studies were done prior to and during treatment. Dosage and duration of administration varied widely in this group.

METHOD

Group 1.—Pretreatment liver function studies had been obtained in three of the five patients in whom jaundice subsequently developed; all had been reported as being normal. In one case the control study had revealed spotty but minimal evidence of hepatic disease. Chlorpromazine was then instituted at low dosage levels and increased progressively as the case warranted. Maximum daily dosage ranged from 100 to 1,000 mg. Use of the drug was immediately discontinued when jaundice became apparent, and serial laboratory tests were done frequently thereafter. These included quantitative van den Bergh determinations, serum alkaline phosphatase, blood cholesterol, urine bilirubin and urobilinogen, cephalin-cholesterol flocculation, thymol turbidity, total serum proteins with albumin-globulin ratio, prothrombin time, and sulfobromophthalein (Bromsulphalein) retention. All tests listed were not done in all patients.

Group 2.—In group 2, 14 patients were given chlorpromazine for varying periods that averaged more than one month. Ten received 25 mg. orally three times a day; four received doses that varied from 25 to 100 mg. given two to four times a day. To detect any possible early biliary obstruction or change in hepatocellular function, the patients were followed at regular intervals with tests of liver function. Typically, these tests consisted of (1) thymol turbidity determinations twice weekly, (2) 48-hour cephalin-cholesterol flocculation determinations twice weekly, (3) direct serum bilirubin determinations twice weekly, (4) urinary bilirubin and urobilinogen determinations three times weekly, and (5) a determination of sulfobromophthalein retention once before or near the beginning of chlorpromazine therapy and at least once after or near the end of therapy. Occasional exceptions to this procedure occurred, most of which were in the nature of laboratory or nursing errors, but these exceptions were taken into consideration in the evaluation of the results. Two pretreatment control studies were obtained in 10 of the 14 patients, one control study was obtained in one patient, and no pretreatment controls were done in the remaining three patients.

Case	Duration of Therapy,* Days	Dose per Day, Mg.			Route of Administration
		Minimum	Maximum	Average	
1	8	200	300	210	Oral
2	17	100	200	123	Oral
3	21	150	200	160	Oral
4	22	150	1,000	660	Oral-I.M.
5	20	200	800	320	Oral-I.M.

* Prior to development of icterus.

Group 3.—The third group, 70 patients, received chlorpromazine for varying periods of time and in varying dosage totals. The average duration was one month, with a range of one week to five months. Dosage ranged from 100 to 1,000 mg. daily. The usual procedure was to initiate therapy at a dose of 25 mg. four times a day, after which it was increased to therapeutically effective level and then reduced. The average maximum reached was 800 mg. daily. Pretreatment controls were obtained in each case and consisted of tests for serum bilirubin cephalin-cholesterol flocculation, and total serum proteins with albumin-globulin ratio. If there was suggestive evidence of any abnormality, further tests were done which included sulfobromophthalein retention and thymol turbidity tests. Thereafter serum bilirubin determinations were done weekly on all patients. In the event of a rise in serum bilirubin level, more extensive tests followed.

RESULTS

Jaundice.—The occurrence of jaundice was erratic appearing sporadically in relatively widespread areas and at various times. An infectious factor was thought to be of little probability. There was no correlation among the factors of age, sex, and diagnosis. The total daily dose did not appear to be a significant factor. The route o administration was usually oral; two of the patients had received the drug intramuscularly during the early phases of treatment. One factor that may be of significance was noted in two of the five cases. In both there was a definite history of allergic skin reactions; both patients developed dermatitis and jaundice during the course of chlorpromazine therapy.

In the majority of cases icterus appeared approximately three weeks after chlorpromazine therapy had been instituted. With the exception of one patient in whom there was a generalized maculopapular eruption, no unusual side-reactions had previously occurred. Premonitory symptoms of the jaundice were generally very mild; the patients, though experiencing general malaise, were in no great distress. In several instances if icterus had not appeared the complication might have escaped detection, for often the complaints were at first attributed to the psychiatric condition. Symptoms usually consisted of persistent or intermittent nausea, vague abdominal pain, and occasionally vomiting. In three patients there was sudden elevation of temperature, which ranged from

100 to 102 F. One patient simultaneously developed a generalized urticaria. Generally these symptoms preceded the appearance of icterus by three to five days, although in one patient there was a two week lag and in another there were no prodromal signs.

The succeeding clinical course in each case was uneventful, disturbing symptoms disappearing within several days, icterus clearing within two to three weeks. Treatment was of a supportive nature, consisting mainly of withdrawal of the drug, intravenously administered glucose when indicated, therapeutic vitamin regimen, and high carbohydrate–high protein–low fat diet. Laboratory findings were characteristically those of obstructive jaundice, with hyperbilirubinemia, elevated serum alkaline phosphatase level and bilirubinuria. Cellular function did not appear to be impaired as determined by cephalin-cholesterol flocculation, thymol turbidity, and total serum proteins with albumin-globulin ratio. Unfortunately, in only one case was prothrombin time obtained; in this instance it was 100% of normal. Chlorpromazine therapy was later reinstituted in one patient who had previously developed both dermatitis and jaundice while taking a total daily dose of 1,000 mg. Neither complication recurred, and liver function tests remained normal.

Hepatotoxic Studies.—There was no evidence that hepatotoxic effects were occurring in the 84 patients studied for possible change in hepatocellular function. In the series of 14 patients who were closely followed by means of comprehensive batteries of liver function tests, there was no clinical or laboratory evidence of development of hepatic dysfunction. Bile excretion, as indicated by determinations of serum bilirubin, urinary bilirubin, and urinary urobilinogen, was not disturbed. Cellular function was likewise not impaired. Isolated increases in cephalin-cholesterol flocculation to abnormal levels (2+ to 3+) occurred during the course of treatment of four of the patients; however, the remainder of their tests were normal, and we were confident that they were experiencing no hepatocellular damage from therapy. Thymol turbidity units varied greatly, although variations generally remained within normal limits. The averages between the control studies and the studies during treatment were in most cases remarkably consistent. Only two patients ever showed thymol turbidity values greater than the normal 5 units. In one values ranged from 4 to 10 units. The mean before treatment had been 5.0; the mean during treatment was 6.2. In the other case a single elevation occurred 23 days after treatment had begun, but subsequent determinations were consistently within normal limits. In both these cases the possibility of liver involvement was discounted on the basis that all other tests remained normal. In the group of 70 patients in whom less extensive liver function studies were done, no changes of significance occurred. Serum bilirubin levels remained normal throughout the duration of therapy in all but three patients. Each of the latter showed a single elevation during the course of therapy, but more extensive batteries failed to corroborate this finding.

COMMENT

On the basis of results obtained in this study it would appear that under ordinary circumstances chlorpromazine *does not interfere with normal liver function.* There is furthermore no evidence that the drug is injurious to the liver cells, even on prolonged administration. *This report has necessarily included only patients* who were followed by serial tests of hepatic function. Not included are over 700 patients, some of whom have been taking the drug for as long as six months, who have manifested no clinical symptoms of liver involvement throughout the duration of therapy.

We are of the opinion that the development of jaundice is an expression of individual drug idiosyncrasy. We have been unable to correlate the appearance of this complication with any factors that we have considered. The process is apparently confined to the bile passages, the liver parenchyma being spared. Although our deductions are based solely on the results of biochemical tests, studies of liver biopsy material by others[2] have revealed occlusion of the biliary canaliculi with stasis of bile and varying degrees of inflammatory cell infiltration but no *parenchymatous change. Chlorpromazine therapy was* reinstituted in one of our patients who had previously developed jaundice, without recurrence. This feature further suggests that rather than toxic specificity of the drug itself, an idiosyncratic, or perhaps allergic, factor exists. Another possible clew may lie in the finding that the only two patients in our series who developed both dermatitis and jaundice had shown allergic reactions to other chemicals in the past. We consider that chlorpromazine is not a specific hepatotoxin and that, in the absence of extenuating factors such as hypersensitivity, hepatocellular function and bile excretion will remain undisturbed.

CONCLUSIONS

Jaundice is an infrequent complication of chlorpromazine [10-(γ-dimethylaminopropyl)-2-chlorophenothiazine hydrochloride] therapy and is believed to be an expression of individual drug idiosyncrasy. The jaundice appears to be due to obstruction within the intrahepatic bile passages, hepatocellular function remaining unimpaired. Preliminary investigation suggests that under ordinary circumstances chlorpromazine is not hepatotoxic and can be administered over prolonged periods of time without undue risk.

Treatment of Acne.—Oral antibiotics remain a useful adjunct in the management of pustular acne. Relapses of the infection are frequent and require repeated courses of therapy. Tetracycline, erythromycin, and carbomycin are effective agents in controlling the pyogenic element of acne. They are well tolerated, with a minimum of side-reactions. Micrococcus pyogenes cultured from [an] acne patient did not show a high sensitivity to erythromycin but evidenced no resistance to it. Erythromycin must be used longer than tetracycline to produce improvement. Carbomycin required even higher doses and more prolonged therapy to be effective. Conventional dermatologic therapy enhanced further the clinical results and the administration of Staphylococcus toxoid also aided in reducing the infectious element.—F. T. Becker, M.D., and M. G. CORTISONE IN IMMEDIATE THERAPY OF APOPLECTIC STROKE

Henry I. Russek, M.D., Staten Island, N. Y., Allen S. Russek, M.D., New York
and
Burton L. Zohman, M.D., Brooklyn, N. Y.

Cerebrovascular diseases still remain among those most neglected because of the fatalistic philosophy commonly associated with their management. It is estimated that there are approximately 1,800,000 sufferers from this affliction in the United States today and that a large percentage of these require one to four persons to take care of their needs.[1] In recent years progress has been made in restoring many such patients to lives of independence and productivity, as a result of the application of modern methods of rehabilitation and retraining.[2] The advances in the therapy of residual paralytic defects by physical methods, however, have far exceeded the questionable gains in the treatment of the acute phase of the cerebrovascular accident.

METHODS OF TREATMENT

The immediate treatment of "stroke" is mainly devoted to measures for saving life and restoring physiological balance. All authorities stress the importance of skillfull nursing care, maintenance of hydration, attention to bladder and bowels, and the prevention of hypostatic pneumonia. In most places the conventional form of therapy is still largely one of expectancy on the part of patients and physicians as well. The current attitude toward therapy has been summarized by Alvarez [3] in a recent editorial as follows: "The best treatment for cerebral thrombosis is an expectant one. We all know that in many of these cases a weakness of the arm or leg clears up, and often aphasia disappears almost entirely. This recovery may be due to subsidence of edema of the brain or it may be due to rerouting of impulses around the destroyed area of the brain tissue."

Nevertheless, despite the recognition that return of function often occurs spontaneously, owing to a clearing of cerebral edema and improvement in cerebral blood flow, there is discontent with the necessity for awaiting expectantly the final and unalterable decree of nature. The hope of decreasing the degree of neurological residua has stimulated interest in a more active treatment of cerebrovascular occlusions. Frequent attempts have bee made to improve the cerebral circulation in such patien by the administration of vasodilator drugs, by the inje tion of procaine into the stellate ganglion, and by the a ministration of anticoagulants. Drugs of the vasodilat group have been found of little value for treatment organic occlusion of the cerebral vessels; on theoretic grounds alone, there is little to suggest that any lasti benefit could result from a short period of vasodilatio When neurological signs and symptoms are the result transient cerebral vasospasm, however, large doses papaverine (0.1 to 0.3 gm., three or four times a day) have great value in the prevention of recurrences.[4] It h been argued that these phenomena are due to minu thrombi or "little strokes," but many, probably a m jority, are based on temporary spasm of the arteries i volved. Many patients are seen who have a series transient strokes that may range in severity from slig numbness or weakness of the side of the face, or slig difficulty with speech, to hemiplegia and that may last a few minutes to several days, with complete recove They may recur repeatedly in the same day in identi fashion. These phenomena frequently portend a ma paralysis with all of its catastrophic effects. The striki clinical improvement that we have reported from the of papaverine in the prevention of these vasospastic e sodes has been supported by observations indicatin substantial increase in cerebral blood flow after the ministration of the drug.[5] Consequently, when premo tory symptoms become manifest, papaverine in la dosage does seem to constitute a rational and effecti preventive measure.

There is a divergence of opinion in the literature as the efficacy of blocking the stellate ganglion. The di culty in differentiating between clinical improvement sulting from therapy and that occurring spontaneou indicated the need for carefully controlled studies. It essential to bear in mind the natural course of this sy drome and the fact that many, if not most, of these p tients show striking improvement during the first we or 10 days. It has been argued that no logical basis exi for blockage of the stellate ganglion, since most observ tions on the circulation of the brain show that the cereb vessels are not under the control of the cervical symp thetic nerves. Scheinberg [6] and Harmel and associate actually found no alteration in cerebral hemodynami after blockage of the stellate ganglion, but it has not be established whether the patients in their study were co parable to those who receive such therapy for clinic purposes. Final evaluation of the indications and us fulness of this procedure must await more extensive e perience.

Anticoagulants have been tried in patients with cer bral thrombosis in an effort to prevent further extensio of preexisting thrombi or the formation of new clots. I

cases of hemorrhage or certain blood dyscrasias, the danger of this form of therapy is obvious. It is also believed that the risk of secondary hemorrhage in a softened area of the brain is increased if the clotting mechanism is disturbed[8]; hence, no definite conclusions are warranted about the value of this form of treatment.

From these considerations it can be seen that no acceptable therapy for stroke is now available to hasten recovery from the acute phase of the attack or to reduce the extent of the cerebral lesion and its associated neurological defects. In earlier studies[9] concerned with the rehabilitation of hemiplegic patients, we observed that the administration of cortisone promoted a sense of well-being, improved motivation, stimulated psychomotor activity, and diminished pain. These desirable actions of the drug permitted early ambulation and shoulder manipulation, even in neglected cases in which there were painful contractures. In all of these patients cortisone was administered many weeks or months after the development of the acute cerebrovascular occlusion. The possibility that cortisone may also have value in the acute phase of the disease immediately after the onset of stroke was suggested, not only by these findings but also by other considerations of a theoretical nature. Many workers[10] have demonstrated that, after administration of cortisone, there is delay in fibrosis, diminished cellular reaction, scanty formation of ground substance, little capillary formation, and complete lack of fibrin and exudate. Inasmuch as local cerebral edema surrounding an area of infarction is commonly regarded as a contributory factor in the perpetuation of neurological signs, the retardation of the mesenchymal tissue response would appear to be a most important and immediate objective of therapy. If this retardation could be achieved, nerve cells that otherwise would eventually die of anoxia as a result of the tissue reaction in the zone surrounding the affected area might be spared, and the ultimate irreversible changes in the brain might be held in abeyance or reduced to a minimum. The probability of such an effect from cortisone in cerebral infarction is strengthened by observations of its influence on tissue response to incision of the brain[11] and on experimentally produced myocardial infarction in animals.[12]

In a preliminary report[13] we recorded the results obtained in 15 consecutive cases of apoplectic stroke that were treated by means of a short course of cortisone, initiated within 48 hours after the onset of symptoms. It was found that cortisone was without benefit in the 3 patients in the series who suffered a cerebral hemorrhage but that it exhibited striking effects in 9 of the 12 patients with hemiplegia due to cerebral thrombosis or embolism. Because of these encouraging results, this method of treatment has been carried out in all patients coming under our care in whom acute cerebral thrombosis or embolism was associated with severe neurological signs. We have treated 35 such patients by steroid therapy. This paper is concerned with the results obtained under this regimen.

CLINICAL MATERIAL AND METHODS

Of the 35 patients in this series, 30 were men and 5 were women. The ages ranged from 40 to 74 years, with a mean of 60.2 years. Hypertension was present in 24 of the 35 patients. A history of angina pectoris was obtained in eight and previous myocardial infarction in seven. The cause of the cerebrovascular occlusion was diagnosed as thrombosis in 27 cases and as embolism in 8. The latter occurred in three patients convalescing from acute myocardial infarction and in five patients with rheumatic heart disease and chronic auricular fibrillation. Twelve of the total group had previously suffered from bouts of congestive heart failure. Diabetes mellitus of mild to moderate severity was present in six patients. In all but three of the total group the signs and symptoms were severe. Eight patients were disoriented or semicomatose at the time treatment was instituted. Eighteen patients showed marked hemiparesis on the right, conjugate deviation of the eyes, and varying degrees of clouded consciousness; marked facial weakness, aphasia or dysarthria, and difficulty in swallowing were found in most of these 18 patients. Four patients exhibited complete flaccid paralysis of the left extremities. Eight patients showed hemiparesis on the left, but, in three of these, the symptoms were of a mild nature. The remaining subjects in the series had marked involvement of the face and upper extremity, but the leg either escaped involvement or was only mildly affected. In most instances 300 mg. of cortisone was administered orally in divided doses on each of the first two days, with progressive diminution to a maintenance dose of 50 mg. daily through the third week. In three patients the course of cortisone therapy was intentionally discontinued at the end of the first week, but in two of these patients it was resumed after several days. Cortisone was administered parenterally in patients who were comatose or who had difficulty in swallowing. In addition, when possible, each patient was given a low-salt diet, with 3 gm. of potassium chloride orally each day in divided doses. Serial observations were made of the electrocardiogram, hemogram, and urinalysis. Repeated daily determinations were made of the blood pressure and heart rate. Serum sodium and potassium levels were not followed. In all patients cortisone therapy was started within 48 hours after the onset of the cerebrovascular accident; in 22 of the 35 patients it was begun within 24 hours after the appearance of symptoms. In three patients (two with cerebral embolism and one with cerebral thrombosis) cortisone was administered after blockage of the stellate ganglion proved ineffective.

RESULTS

In 21 of the 35 patients in this series dramatic clinical improvement was noted within 24 hours after the commencement of cortisone therapy. There was not only a striking amelioration of paralytic signs and symptoms but also unquestionable benefit from changes in the mental, emotional, sensory, and psychomotor status. Conjugate deviation of the eyes, incoherent speech, dysarthria, and aphasia appeared to clear rapidly during cortisone therapy. The greatest effects were noted among those who were somnolent, stuporous, mentally depressed, or apathetic. In 19 patients so afflicted, these symptoms were replaced overnight by a keen alertness and sustained interest in personal progress. Accompanying these mental changes, there was noteworthy subsidence in the degree of paresis of affected extremities, as shown by significant increase in the range of motion and in the ability to perform various activities. Moreover, active rehabilitative measures were easily instituted after only one or two days of treatment as a consequence of the rapid recovery from acute mental disturbances, associated with improved motivation, psychomotor stimulation, and increased sense of well-being. The greatest clinical improvement in all cases occurred within the first 24 to 48 hours after cortisone therapy was started; thereafter, definite but more gradual return of function ensued. The most marked benefits from the drug were observed in the more severe cases of cerebral thrombosis and embolism; however, in four patients with complete flaccid paralysis of involved extremities, no improvement in motor power was noted in response to the drug, although unmistakable benefit in the psyche was apparent. Cortisone therapy was intentionally discontinued in three patients after approximately one week of therapy; in two of these paresis increased in the involved extremities after the drug had been withheld for two and three days respectively. The readministration of cortisone, however, was soon followed by improvement in the motor power of the affected limbs. No such rebound phenomenon was observed at the termination of therapy in any of the patients receiving cortisone continuously for the three week course. At the end of this period remarkable neurological recovery had occurred in 27 of the 35 patients in the total group. In these, residua consisted of mild to moderate weakness in the handgrip, mild foot-drop, lower facial paresis, and minor difficulties in speech and deglutition. No serious difficulties were encountered from the use of cortisone in this study.

COMMENT

It is acknowledged that a rapid and nearly complete recovery may occur after a cerebrovascular accident, with nothing more than symptomatic treatment. Nevertheless, the frequency of prompt and striking improvement in neurological symptoms in our patients with cerebral thrombosis or embolism during cortisone therapy must be regarded as more than coincidence. Cortisone appeared to convert the discouraged, apathetic, or bewildered hemiplegic to a cooperative, hopeful, and even mildly euphoric patient overnight. Clouded consciousness, stupor, and disinterest in surroundings were often replaced within 24 hours by a degree of alertness and insight not encountered at any time in apoplectic patients treated expectantly. The clinical impression obtained was that cortisone accomplished in one day what ordinarily might take several weeks with conservative treatment. These beneficial changes in the psyche of individual patients in response to cortisone seem indisputable and leave little doubt as to the value of the drug in this disorder. Moreover, the marked subsidence in paralytic signs and symptoms that frequently accompanied the striking mental changes may also prove to be directly attributable to the action of cortisone. Two of the three patients in whom cortisone therapy was prematurely stopped showed increasing paresis, with reversal of effect when therapy was resumed.

With cortisone therapy rehabilitative measures can be instituted with little difficulty after only one or two days of treatment because of the patient's alertness of mind and euphoria. The early employment of retraining methods undoubtedly played a part in the remarkable neurological recovery observed in most of these cases, but since the major response was observed before the application of such measures, the effect of the cortisone on the apoplectic lesion in the brain itself should be considered It is of interest that cortisone appeared to exert its maximum influence in the more seriously ill patients with cerebral thrombosis or embolism. Patients with milde cases responded satisfactorily, but the most dramatic effects were noted in patients with marked hemiparesis aphasia, conjugate deviation of the eyes, and cloude consciousness. These findings support the impressio that the immediate effects of cortisone are more marke in patients with the more extensive lesions of the brai in which local edema plays a prominent part. Obviously any method capable of preventing or eliminating th interstitial edema that is an outstanding gross and microscopic characteristic of apoplectic lesions would preserve nerve cells and permit a greater degree of neurological recovery. The probability of such an effect fro cortisone is further suggested by observations of its a tion on experimentally produced myocardial infarcts animals.[12] Thus, in the treated animal there was a shar line of demarcation between the area of infarction an the adjacent muscle, whereas in the control there was broad, irregular zone of healing. Postmortem injectio studies furthermore demonstrated a greater developmen of collateral circulation under the influence of cortisone Similar observations on the incised brains of animals hav demonstrated an inhibitory effect of the drug on interstitial edema.[11] Regardless of the explanation, administration of the drug appears to counteract some of the immediate effects of stroke due to cerebral thrombosis o embolism. In a disease that is commonly viewed with a fatalistic philosophy and treated at best with good nursing care, cortisone should prove a most valuable addition to therapy and a useful adjunct for early rehabilitation

In the present series of cases no significant complications were observed from the administration of cortisone. In patients with diabetes mellitus the diabetes was easily controlled by meeting the increased demand for insulin. Clinical signs of sodium retention were not observed, and hypertension was not aggravated by the use of cortisone. Although well over 100 cases of cardiovascular or cerebrovascular disease have been treated to date with cortisone by the authors,[14] no thrombotic incident has occurred in any patient during the course of therapy or in the immediate post-treatment period. This experience in patients with obvious thrombotic tendencies and with advanced vascular disease does not confirm the alleged risk of thromboembolic complications from the use of this drug.[15]

Int. Med. 91: 487 (April) 1953; Russek, H. I.; Zohman, B. L., and Russek, A. S.: Risk of Thromboembolic Complications from Cortisone Therapy, Am. Heart J. 47: 653 (May) 1954.

SUMMARY AND CONCLUSIONS

Various attempts have been made to improve the cerebral circulation in patients with apoplectic stroke, in the hope of decreasing neurological residua. The uncertain responses with such methods have left no alternative to expectant therapy. Inasmuch as cortisone has been found of value in the rehabilitation of hemiplegic patients, through its action in enhancing motivation and promoting a sense of well-being, it was considered logical to make a trial of the drug for the acute cerebrovascular accident. Moreover, since local cerebral edema is believed to be a contributory factor in the perpetuation of neurological signs, and since cortisone has been shown to retard the mesenchymal tissue response to various forms of trauma, additional benefit from cortisone seemed possible in this respect. With these objectives in mind, 35 cases of apoplectic stroke due to cerebral thrombosis or embolism were treated with this drug within 48 hours after the onset of symptoms. Cortisone produced striking effects in 21 of the 35 patients under this regimen, and remarkable neurological recovery had occurred in 27 patients by the end of the third week of cortisone administration.

Cortisone is a valuable addition to the therapy of acute cerebral thrombosis or embolism. The drug appears to offer a dynamic approach to limiting the assault of a disease that, until now, has been viewed, at best, with expectancy, and, at worst, with defeatism. No significant untoward effects from cortisone were noted in this study.

TOXEMIA OF PREGNANCY AS AN ETIOLOGICAL FACTOR IN HYPERTENSIVE VASCULAR DISEASE

Phil C. Schreier, M.D., John Q. Adams, M.D., Henry B. Turner, M.D.
and
M. Jean Smith, M.D., Memphis, Tenn.

Although many reports have appeared describing follow-up findings in thousands of patients with previous toxemia of pregnancy, no clear-cut answer can be found to the question of whether toxemia of pregnancy is an etiological factor in the development of permanent hypertensive vascular disease. The variation in available data is illustrated by the fact that previous reports have placed the incidence of hypertension following toxemia from 0 to 78%. The average reported incidence following preeclampsia is 45%, and that following eclampsia is 22.5%, approximately one-half as much. This tremendous variation might be explained in part by the lack of uniformity of criteria for a diagnosis of toxemia and post-toxemic hypertension. The reported level of blood pressure constituting hypertension has varied from 130/70 to 170/100 mm. Hg. Today most investigators consider 140/90 mm. Hg as the dividing line between a normal blood pressure and hypertension. Master, Dublin, and Marks[1] have shown that the level of blood pressure considered to be normal rises with increasing age and that it is incorrect to say that a blood pressure of 140/90 mm. Hg constitutes hypertension for all age groups. Even though considerable confusion exists regarding post-toxemic hypertension, interpretation of the available data tends to fall into two general schools of thought. The evidence in favor of the theory that toxemia of pregnancy leads to permanent hypertension is vastly more abundant and overwhelming than the evidence in support of the theory that it does not lead to permanent vascular damage.

LITERATURE ON TOXEMIA, PREECLAMPSIA, AND ECLAMPSIA

Among the early reports suggesting that hypertension followed toxemia was that of Harris,[2] who in 1924 reported that of 55 women with preeclampsia 60% showed signs of chronic hypertensive renal disease one year later. Peckham[3] found that 22.1% of 77 women who had eclampsia one year previously had "chronic nephritis." This he thought represented sequelae to the previous toxemia. He recognized the fact that more damage occurred after severe preeclampsia than after mild preeclampsia. The diagnosis of chronic nephritis was made on the presence of hypertension and proteinuria. We now know that this probably was not chronic nephritis in the true sense but chronic vascular renal disease. There is general agreement that chronic glomerulonephritis is a rare complication of pregnancy. The work of Chesley on the problem of post-toxemic hypertension has been perhaps the most outstanding. His results are especially reliable because of his intense interest in this subject for many years and the thoroughness with which his studies were done. In 1941 he reported

that the gross incidence of hypertension following nonconvulsive toxemia was 53% and the recurrence rate of toxemia was 46%.[4] Of special interest are the repeated follow-up findings among patients with eclampsia treated over a period of 15 years at the Margaret Hague Hospital. In 1941 Chesley and Somers [5] reported that only 17.5% of these patients had permanent hypertension. Seven years later Chesley, Somers, and Vann [6] found the incidence of permanent hypertension in 245 patients with previous eclampsia to average 15%. The average rate of recurrence of toxemia in this series was 44.7%, with eclampsia recurring in only 2.3%.

Peters [7] has said that "toxemias of all kinds leave behind them marks, usually in the vascular system that cannot be eradicated." The idea that anoxia, developing as a result of prolonged vasospasm, leads to permanent, irreversible structural damage to the vessel wall has been accepted by many, including Eastman, Page, and Chesley. Glomerular lesions in acute toxemia have been observed and described as a thickening of the basement membrane. Page and Cox [8] examined the kidneys of eight patients dying with toxemia and seven patients with previous toxemia; he found the same glomerular damage in both groups. This constitutes evidence of structural damage that did not revert to normal. Govan, however, reported that such changes were also found in the kidneys of patients dying of nontoxemic disease during pregnancy.[9]

The following factors are recognized as influencing the development of permanent hypertension following toxemia: family history, height of blood pressure during the toxemia, state of gestation at which toxemia developed, parity, age at time of toxemia, age at time of follow-up examination, duration of toxemia, and the weight of the patient. Of these, we feel that the most important are the duration of the toxemia and the age at the time of the follow-up examination. It has been shown repeatedly that the incidence of permanent hypertension increases directly with the duration of the toxemia.[10] Page [11] believes that the duration is important and says that a moderate preeclampsia of three weeks' duration will produce more damage than a severe preeclampsia of one week's duration. It is generally agreed that after three weeks' duration the incidence of permanent hypertension rises rapidly and that the earlier in pregnancy toxemia develops the more likely the patient is to be left with permanent hypertension. This is probably because those developing toxemia early will be treated longer in order to obtain a viable fetus. This still points to duration as the significant factor. An increasing percentage of pateints will become hypertensive if followed for many years. Without consideration of the effect of age, erroneous conclusions could be drawn from long-range follow-up examinations showing small increases in permanent hypertension.

The chief advocate of the other side of this question has been Dieckmann. For 20 years he has contended that toxemia does not produce permanent hypertension and that, if hypertension, albuminuria, and edema persist for two weeks despite adequate treatment, the disease is not preeclampsia but essential hypertension.[12] Dieckmann delays the final diagnosis until the follow-up examination, and, if the patient is found to have hypertension or albuminuria, the diagnosis then becomes chronic vascular renal disease regardless of the clinical picture during the acute episode. He goes so far as to say that the convulsions in such a situation are possibly from hypertensive encephalopathy. In 1952, Dieckmann, Smitter, and Rynkiewicz [13] published a report reviewing the factors influencing recurrent toxemia and post-toxemic hypertension but did not prove the contention of the title, "Pre-Eclampsia-Eclampsia Does Not Cause Permanent Vascular Renal Disease." Some investigators have written reports supporting Dieckmann's theory. Theobald showed that there was no significant difference in deaths between parous and nulliparous women as a result of cardiovascular renal disease. Barnes and Browne [14] and Isenhour, Kuder, and Dill [15] found little difference in hypertension among parous and nulliparous patients. However, Chesley's rebuttal to this is especially interesting. He points out that the 1% higher incidence of hypertension in parous women from the pooled data of these two reports is of the right magnitude to take in the effect of toxemia.[10]

Some investigators have said that patients with hypertension at the time of follow-up examination would have been so regardless of the pregnancy or the toxemia. Others concede that toxemia may precipitate hypertension earlier than would be expected, even though the individual was destined to become hypertensive. The idea that toxemia is an acute form of an underlying hypertensive tendency has also been expressed. We would agree with Chesley that the use of terms such as "latent hypertension" or "destined for hypertension" is to be questioned. How can one say that the development of hypertension in any patient is inevitable? It is recognized that the problems of recurrent toxemia and permanent hypertension are closely related. Few patients with repeated episodes of toxemia escape the sequelae connected with permanent vascular damage. Dieckmann has expressed the opinion that a recurrence of toxemia is not toxemia at all but vascular renal disease.

Other investigators have said that repeat toxemia is a different and perhaps milder syndrome than the initial syndrome.[16] Young,[17] on the other hand, stated that a recurrence of toxemia is in no wise different than the original syndrome. It is difficult for us to see how two episodes with identical manifestations could be considered as having any essential differences.

The problem of recurrent toxemia was first recognized by Gibson in 1921; however, the term recurrent toxemia was not applied until three years later, when Kellogg[16] described the syndrome that he thought was due to a renal insufficiency. This line of reasoning led to the introduction of the term "low reserve kidney" by Stander and Peckham. This was an unfortunate term, as it implied an inadequacy that did not exist. The thinking of this era was further expressed by one of us (P. C. S.),[18] who reported on four patients illustrating the problem of recurrent toxemia. The problems of toxemia of pregnancy and recurrent toxemia with their relationship to permanent vascular renal disease are so paramount that all centers with considerable experience in toxemia should analyze their experience in an effort to provide an answer to these complex questions. Chesley has said that he does not believe an answer will be found in the follow-up studies. We might add, perhaps, that there is no answer; however, out of such studies will come information that can be used as a prognosis for both infant and mother, as well as information as to the advisability of future pregnancies. It is the purpose of this report to focus attention on these problems and to add our experiences from the City of Memphis Hospitals.

MATERIAL

In an effort to eliminate the possibility of including patients with preexisting hypertension or previous toxemia in the study, only primigravidas with normal blood pressure in early pregnancy and negative cardiac histories were selected. These women were followed in our prenatal clinics and subsequently developed some degree of toxemia in their first pregnancy. Follow-up through successive pregnancies for 5 years was carried out in one group, and, in another, the patients were observed for 10 years. The factor of advancing age, therefore, could be appraised. The mean age at the initial pregnancy was 18 years for each group. A random sample of 340 hospital charts was selected for study on the basis of proved toxemia in the first pregnancy and follow-up of at least five years or more. After additional study, 101 of this number were discarded for lack of complete information. The remaining 239, it is felt, represent cases of pure toxemia of pregnancy that occurred in the first gestation of otherwise normal females. Data included the occurrence of repeated bouts of toxemia, the incidence of elevated blood pressure without albuminuria or edema, and the occurrence of permanent hypertension following pregnancy. The number of pregnancies and the frequency of repeated toxemia were correlated with age and the finding of persistent hypertension. No attempt was made to correlate duration of toxemia with the development of residual hypertension. No racial distinction was attempted, but more than 95% of the total were Negroes.

The principal difficulty in considering recurrent toxemia of pregnancy as a factor in the etiology of essential hypertension is the necessity of establishing a base of comparison. A certain number of any group would develop permanent hypertensive vascular disease with or without toxemia of pregnancy. The contributions of Master, Dublin, and Marks[1] are the best data yet available as to hypertensive expectancy. In their studies of more than 7,000 women in industry, many of whom were nulliparas, it was established that an increasing percentage of women develop essential hypertension in the advancing decades of life. Blood pressure of 140 mm. Hg systolic and 90 mm. Hg diastolic or above was used by Master as the criterion for the diagnosis of hypertension, at ages 25 to 29 years. He found that 8.4% of his patients had persistently elevated blood pressure. The mean age of our patients at the time they were found to have residual hypertension was 26 years. In the absence of an ideal group, they will be compared, therefore, with Master's group of the same age.

FINDINGS

Five Year Group.—A total of 142 tabulations was made on patients followed for five years after the initial episode of toxemia. Of this number, 59 had mild preeclampsia in their first pregnancy, 63 had severe preeclampsia, and 20 had eclampsia. The fact that twenty of 142 patients had eclampsia showed the apparent result of random selection; such a high percentage of convulsive toxemia does not reflect the true incidence of this disease in our patients. Of the entire group, 35.2% had recurrent toxemia in subsequent pregnancies. Fourteen per cent had blood pressure elevations in excess of 140 mm. Hg systolic and 90 mm. Hg diastolic but had no edema or albuminuria. These were considered in a separate group because they did not fulfill the diagnostic criteria of toxemia yet it was felt that the temporary hypertensive episode might be of prognostic importance. A total of 50% of the group, therefore, had recurrent temporary hypertension. Fifty-three patients, or 38% of the group, had no recurrent toxemia or hypertension. Seven patients had no further pregnancies. Ten patients, or 7% of the total tabulated, were found to have a permanent elevation of blood pressure at the end of the five year period.

Table 1 shows the correlation between the severity of the initial episode of preeclampsia and the incidence of recurrent toxemia. Furthermore, permanent hypertension occurred in only 3.4% of those having mild preeclampsia, while those with an initial diagnosis of severe preeclampsia composed 11.1% of the group. When the initial diagnosis was eclampsia, this trend was reversed, and only 5% of the patients eventually developed essential hypertension. The implication is that duration of toxemia has a bearing on the development of permanent hypertension. This has been demonstrated by others but is not included in our data, for many of the patients herein reported on were followed in outlying clinics and the specific time of onset of symptoms could not be reliably obtained.

[18] Schreier, P. C.: A Discussion of the Recurrent Toxemias of Pregnancy, Mississippi Doctor 11: 29, 1934.

Ten Year Group.—Ninety-seven tabulations were made on patients followed for 10 or more years. Of these, 67 had mild preeclampsia, 24 had severe preeclampsia, and 6 had eclampsia (table 2). Of the entire group, 30.9% had recurrent toxemia in later pregnancies and 11.3% had a temporary elevation of blood pressure. Persistent hypertension was found in 17.5%. This finding was no surprise, for the mean age in this group was higher than that of the five year group. The simple factor of advancing age would explain part of this increase over the 7% in the first group found with residual hypertension. Again, there was a definite correlation between severity of the initial attack and the development of permanent hypertensive disease. Whereas 10.4% of patients with mild preeclampsia developed hypertensive disease later in life, 41.6% of those with initial severe preeclampsia showed evidence of permanent hypertension at the end of 10 years. None of the 6 patients having eclampsia were later found to have essential hypertension.

TABLE 1.—*Correlation Between Severity of Preeclampsia, Duration of Toxemia, and Development of Permanent Hypertension in 142 Patients Followed for Five Years*

	Mild Preeclampsia		Severe Preeclampsia		Eclampsia		Total	
	No.	%	No.	%	No.	%	No.	%
Recurrent toxemia..	18	30.5	27	42.8	5	25	50	35.2
Recurrent hypertension..	10	16.9	9	14.3	2	10	21	14.8
Recurrent eclampsia... ..	..	....	..	....	1	5	1	0.7

Permanent hypertension.	2	3.4	7	11.1	1	5	10	7.0
Total..	59		63		20		142	

For the two groups combined (table 3) it was found that 33.5% had recurrent toxemia and 13.4% a temporary recurrent hypertension without edema or albuminuria. Twenty-seven patients were found to have permanent hypertension. This represents 11.3% of all cases studied and may be compared to the findings of Master of 8.4% of women between the ages of 25 through 29 years with hypertension. This difference, therefore, represents an increase in incidence of hypertensive disease in our patients over that expected and would be greater if we were able to eliminate those in the control group who had previous toxemia of pregnancy.

TABLE 2.—*Correlation Between Severity of Preeclampsia, Duration of Toxemia, and Development of Permanent Hypertension in Ninety-Seven Patients Followed for Ten Years*

	Mild Preeclampsia		Severe Preeclampsia		Eclampsia		Total	
	No.	%	No.	%	No.	%	No.	%

Total................	67		24		6		97	

Patients Developing Permanent Hypertensive Disease.—A more detailed study of the 27 patients who developed essential hypertension after having had toxemia is revealing. The median age was 26 years at the time permanent hypertension became evident. It is entirely possible that some of these patients developed sustained hypertension prior to the time they were seen in our clinic during their subsequent pregnancies, but, because we have no proof other than the information given in the charts, this is the date and the age recorded. In other words, any error would be in the direction of their having developed hypertension at an earlier age than was noted. It has been our clinical observation that patients who develop permanent hypertension do so most often after several episodes of toxemia. In the figure it can be seen that hypertension occurred more frequently after the patient was exposed to three or more pregnancies and two or more episodes of toxemia. Of the 27 patients, 9 had an initial episode of mild preeclampsia, 17 had severe preeclampsia, and 1 had eclampsia. This means that 6.9% of the total number with mild preeclampsia developed hypertension as compared with 19.5% of those with severe preeclampsia and 5.0% of those with eclampsia. It would appear, therefore, that hypertension is three times as likely to follow severe preeclampsia than it is the milder form of the disease. By contrast, eclampsia very infrequently results in sustained elevations of blood pressure.

Relationship of hypertension to occurrences of pregnancy and toxemia.

SUMMARY AND CONCLUSIONS

A group of 239 patients with "pure" toxemia of pregnancy, developed during their first gestation, has been followed for periods of from 5 to 10 years. All but 11 had subsequent pregnancies. A high percentage suffered recurrent toxemia, and 27, or 11.3% of the total, were found to have permanent hypertensive disease. The expected incidence of hypertension for young women of this age is only 8.4% according to Master and his group. This figure is, in all likelihood, higher than the true incidence of hypertensive disease in women of this age. It must be appreciated that many of the observations of Master and co-workers were made at a time when these women were applying for jobs, a time when slight elevations of blood pressure are common. It is concluded, therefore, that toxemia of pregnancy results in an increased incidence of hypertensive disease and that the more severe the initial illness, excluding eclampsia, the more likely there is to be eventual permanent vascular damage. Repeated pregnancies and recurrent episodes of toxemia may have some relationship to the later occurrence of hypertensive disease, in that most women developing permanent elevation of blood pressure did so after three pregnancies and at least two bouts of toxemia.

ACCIDENT PREVENTION IN CHILDHOOD—THE KEROSENE HAZARD

Hugh A. Carithers, M.D., Jacksonville, Fla.

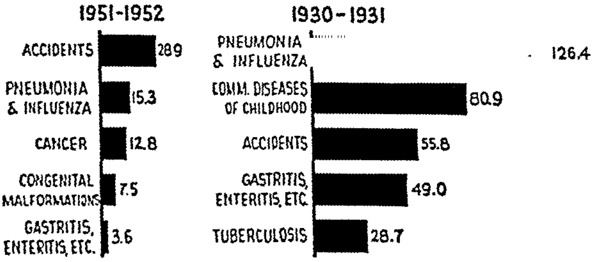
Accidents have become the leading cause of death among children over one year of age.[1] The prominence of accident mortality is due in part to the widespread use of chemotherapeutic agents and immunization procedures, which have helped control communicable diseases and many other acute infections in childhood. Pneumonia, diarrhea, and enteritis—at one time the commonest causes of death among young children—have been gratifyingly controlled. In fact, pneumonia, diarrhea, measles, diphtheria, whooping cough, scarlet fever, meningitis, and poliomyelitis, all combined, do not kill as many American children as do accidents.[2] One-third of all deaths in children at the present time result from accidents, while in 1900 accidents caused only one-twentieth of the deaths occurring in childhood.[3]

There has been, in recent years, some reduction in deaths from accidents among children, but to a much less extent than from diseases (see figure). Since 1930 deaths from communicable diseases have been reduced 97%, from gastroenteritis 93%, from appendicitis 91%, from tuberculosis 89%, and from pneumonia and influenza 88%, but from accidents only 48%. This reduction in accidents does not necessarily mean, however, that children are being injured less frequently. Today physicians are saving more who have been burned, poisoned, crushed, or mangled. Over one-half of all fatal accidents in childhood occur among children under 5 years of age. Dietrich[3] emphasized that the greatest efforts at accident prevention should be made in this age group, not only because these children have more accidents, but because education for safety is more fruitful when directed toward young children. Accidents in the 1 to 4 year age group have risen in prominence as a cause of death. In 1930-1931 pneumonia, influenza, and the common communicable diseases of childhood ranked above accidents with the gastrointestinal diseases not far behind. In 1951-1952 accidents were in first place, almost doubling in number the deaths from pneumonia and influenza, the next ranking group. This, however, is not the whole picture. It has been estimated by authorities[4] on the accident problem that for every fatal accident among children there are at least 100 nonfatal accidents, 4 of which result in some permanent disability.

The table shows the distribution of the principal types of accidents among children aged 1 to 4 years. Although motor vehicles, burns, drowning, and falls all precede poisonings as causes of death, this cause nevertheless gives rise to an extremely important aspect of the problem and illustrates its magnitude. Poisonings are most likely to occur in children of ages 1 through 2 (see table). This is the age of inquisitiveness when some children will eat or drink almost anything.

KEROSENE POISONING

One of the commonest, though not most fatal, types of poisoning among young children is caused by the consumption of petroleum oils, principally kerosene. Bain[5] in her study of accidental poisonings in children under 5 years of age in the United States found that petroleum products accounted for 25% of accidental poisonings in this age group. The Florida Children's Commission in cooperation with the Florida chapter of the American Academy of Pediatrics and the Florida Pediatric Society recently sent a questionnaire to 156 hospitals in Florida in an effort to determine the incidence of poisonings within the state caused by ingestion of volatile oils. Of 90 hospitals returning the questionnaire, 79 accepted children who might be poisoned. In 1953, 229 children, all under 6 years of age, were admitted to 45 hospitals for treatment because of poisoning by volatile oils. Nearly all of these children were



Leading causes of death in children aged 1 to 4 years. Death rates per 100,000. Cancer includes leukemia and Hodgkin's disease.

Read before the Eighth Clinical Meeting of the American Medical Association, Miami, Fla., Dec. 1, 1954.

The statistics in the figure and table are based on experiences of the Metropolitan Life Insurance Company, Industrial Department.

5. Bain, K.: Death Due to Accidental Poisoning in Young Children. J. Pediat. **44**: 616-623 (June) 1954.

poisoned by drinking kerosene. In addition, 78 children were treated as outpatients in 18 hospitals, and it was estimated by 24 hospitals that 288 others probably were treated. Thus a total of over 500 Florida children were treated in that one year for volatile oil poisoning, caused in nearly all cases by ingestion of kerosene. There was only one death among this group. An examination of data from the bureau of vital statistics of the Florida State Board of Health, however, showed that four other children met death in the state in 1953 from drinking petroleum products. They were not treated in the reporting hospitals. These fatalities indicate, in all probability, a much larger incidence of this type of poisoning than was discovered as a result of the questionnaire.

A detailed study was made of all cases of poisoning from petroleum oil products recorded at one of the reporting hospitals, the Duval Medical Center, Jacksonville. During 1953, 76 patients were treated on the charity children's service, one of whom died. The mean hospital stay of these children was 4.53 days. The per diem cost of patient care in this hospital in 1953 was $12.36. If, on the basis of this per diem cost and this average hospital stay, one computes the cost of hospitalizing the known 229 patients treated in Florida hospitals in 1953, he finds that hospitalization cost approximately $12,800. The cost in terms of psychological trauma to the young child and his parents, of course, cannot be measured.

Percentage Distribution, by Principal Types, of Deaths from Accidents Among Children One to Four Years of Age, 1951-1952

	Age, Yr.				
Type of Accident	1-4	1	2	3	4
Accidents—total no. of deaths	753	203	189	188	173
Death rate per 100,000	28.9	....*	.. .*	....*	....*
	% of Deaths				
Motor vehicle—total	37.2	26.6	31.7	45.2	46.8
Run over or hit by motor vehicle	26.8	17.7	22.2	31.4	37.6
Burns and conflagrations—total	19.9	24.6	21.2	18.6	14.4
Conflagrations	10.7	11.8	13.2	10.1	7.5
Burns (excluding conflagrations)	9.2	12.8	8.0	8.5	6.9
Liquid, steam, hot substances, etc.	4.9	8.9	6.3	2.7	1.2
Drowning	15.4	12.3	17.5	13.3	19.1

* Not available.

Kerosene ingestion is not a type of poisoning confined to the South, although it is probably commoner in this area than in other sections of the country. In June, 1953, the committee on accident prevention of the American Academy of Pediatrics reported a survey of 507 cases of accidental poisoning that occurred throughout the United States. In this series kerosene was the second commonest toxic agent, comprising 16% of the total.[6] A review of 375 cases of poisoning recorded in six Chicago hospitals during a recent nine month period, made by the poisoning control committee of the Illinois chapter of the American Academy of Pediatrics, disclosed that in 46 cases, or 12%, the cause of the poisoning was the ingestion of petroleum distillates, principally kerosene.[7]

In the Jacksonville area kerosene is widely used fo heating homes as well as for cooking. Consequently, decided rise in cases of poisoning during the winte months would be expected, but for many years ther have been numerous cases in the wards during the summer. Throughout 1953, for example, the distribution o kerosene-poisoning cases at the Duval Medical Cente was fairly equal, as shown in the following tabulation:

January	5	July	6
February	4	August	7
March	5	September	2
April	7	October	6
May	10	November	12
June	5	December	8

Although there may be more kerosene in the child's environment in the winter, it is during the summer that h will be more likely to drink it because of thirst. This observation emphasizes an important principle in the prevention among young children of poisoning from al toxic liquids: active youngsters should be given fluid between meals, especially in hot weather, so that thirs will not be the stimulus to the consumption of liqui poison.

It is not the purpose of this paper to present a complete discussion of kerosene poisoning. Certain controversial features of the disease, however, are reviewe here because they may have a bearing on surviva Deaths from kerosene poisoning may be due to tw causes: (1) aspiration with pneumonitis, subsequen pulmonary edema, and secondary infection of the lung and (2) toxic effects on one or more organs or system of the body, in particular the liver, stomach, and intestinal tract, and especially the brain. The lungs ar almost invariably involved in severe cases, and it i now believed that aspiration is far more important tha is absorption in causing damage to the lungs. In experimental animals pulmonary damage can be produce by the injection of kerosene intravenously. Some experimenters believe it also can be produced by injectio of the oil into the gastrointestinal tract when the possibility of aspiration is removed.[8] Practically speaking blood levels in man probably never would reach those produced in experimental animals when kerosene is injected intravenously. If there is pulmonary irritation from absorption alone, it is probably not, great. Children who have consumed more than several ounces of kerosene quickly show signs of toxicity with drowsiness and later coma. Kerosene contains hydrocarbons commonly used in some anesthetics, but varies considerably in coma-producing ability because of variability in refining processes.

TREATMENT

The immediate problem facing all physicians treating children who have consumed kerosene is whether or not to aspirate the stomach. The condition of the child, and to a less extent the history, will serve as a practical guide in each individual case. If one can be sure only a small amount was swallowed, if vomiting has occurred, and if there are no signs of toxicity with drowsiness, the child is probably best left alone. On the other hand, if toxic signs, especially with dizziness, drowsiness, or coma, are present, or if someone actually saw him drink a considerable quantity, careful lavage of the stomach, with the head and chest lowered, is indicated. Pinching off of the tube, quick withdrawal, and, if possible, avoidance of vomiting during lavage are important points in technique.

ACCIDENT PREVENTION

This brief report on poisoning from petroleum distillates in one state serves not only to illustrate the magnitude of the problem of poisoning among children but to stress particularly the importance of accidents, of all types, as a cause of morbidity and mortality among the young. No attempt has been made to discuss many important facets of the accident problem, such as accident proneness, for example. The fact that 20% of the accident victims, in some groups studied, sustained over 50% of the accidents is important to physicians.[9] Accident repeaters should have a physical appraisal with special emphasis on vision, hearing, orthopedic status, and neurological integrity. Detailed psychological investigation may be necessary for those having no physical basis for repeated accidents.

All physicians who give medical care to children have an opportunity, indeed a responsibility, to promote accident prevention among them. General practitioners, who provide most of the medical care children receive, have especially good opportunities to promote safety. Becoming safety-minded and teaching safety to parents and children should entail little, if any, additional burden to the busy physician. Some specific suggestions of proved value in accident prevention that doctors can make a part of their routine practice are given below.[10]

1. Education of parents in accident prevention should begin before the child learns to walk. Mention the common home accidents at well-child check-ups, whether in private office or clinic. Distribute pamphlets on accident prevention; they are available for the asking from several leading insurance companies and the National Safety Council. When such literature is left on waiting room tables, it does little good, but when given to a parent with firm instructions, "Read this," it can be of value. 2. On calls in the homes of children, observe unsafe conditions and suggest corrective measures. 3. When treating a patient for any accidental injury, inquire into the cause of the accident and tactfully point out how a recurrence can be prevented in the future. There is no better time than while treating an accidentally injured child to make the parents and the child himself aware that safety measures are of value. 4. In prescribing drugs, stress the dangers of injudicious use and careless storage. This is also a good time to inquire about the handling of harmful cleaning agents, insecticides, and fuel in the home. 5. When a child has repeated accidents, make a complete appraisal of the patient and his environment in an attempt to find the cause. Public health nurses may be of value in such a study. 6. As a guardian of public health and well-being, be a leader in community projects directed toward safety and accident prevention.

CLINICAL NOTES

NEW METHOD FOR LOCAL ANESTHESIA IN PERORAL ENDOSCOPY

PRELIMINARY REPORT

Hubert J. Adler, M.D., Phoenix, Ariz.

Current methods of local anesthesia for peroral endoscopy are unsatisfactory because of (1) the toxic results of the effective surface anesthetics, (2) the discomfort—to put it mildly—to the patient caused by peroral endoscopies under local anesthesia, and (3) the lack of relaxation of the structures underlying the mucosa of the pharynx and larynx. A surface anesthetic does not relax the deeper structures such as the base of the tongue and the cricopharyngeus muscle (the "pinchcock of the esophagus"). The upper front teeth and their gums remain sensitive to the unavoidable pressure of the endoscope. The patient with long upper teeth and/or a short, muscular neck is a dreaded prospect for peroral endoscopies.

I have devised a method whereby the conventional surface anesthetics can be avoided almost completely. The usual preoperative medication (barbiturates, narcotics, and atropine) is given. The area to be described below is anesthetized by injecting a procaine-hyaluronidase mixture (150 turbidity-reducing units to 30 cc. of 1% procaine) or a 2% lidocaine (Xylocaine) hydrochloride solution and by instilling a 5% hexylcaine (Cyclaine) hydrochloride—2% tripelennamine (Pyribenzamine) mixture (ratio of 3:1) into the tracheobronchial tree.

The superior laryngeal nerve is injected first. If one prefers the external approach, the space between the cranial border of the thyroid cartilage and the hyoid bone is palpated. A 1½ in. 23 gauge needle is inserted perpendicularly to the skin 0.5 cm. anteriorly to the superior cornu of the thyroid cartilage until a resistance (the thyrohyoid membrane) can be felt (see table, injection 1). Then the greater palatine canal is injected. The oral opening of this canal lies about 1 cm. medially to the second molar and 1 cm. anteriorly to the border between the hard and soft palate. It suffices to enter the greater palatine canal for a depth of 1.5 cm. This reaches the anterior, middle, and posterior palatine nerves, resulting in anesthesia of the hard and soft palate, uvula, and anterior pillars (see table, injection 2a). An alternate method is to inject the mucosa over-

---

From the Veterans Administration Hospital.

lying the oral opening of the greater palatinal canal without entering the canal proper (injection 2b). The ensuing anesthesia covers a smaller area than the one produced by injection 2a. Injection 2b should be supplemented with an injection into the incisive fossae above the upper incisor teeth (injection 3). This mitigates the pressure of the endoscope on the upper front teeth.

The glossopharyngeal nerve is injected by piercing the anterior palatinal pillars 1 cm. lateral to their free border and carrying the tip of the needle to a depth of about 1.5 cm., where a resistance can be felt. This usually relaxes the base of the tongue (injection 4). Should the base of the tongue remain sensitive, both lingual tonsils ought to be injected (injection 5). The base of the tongue is then depressed downward and forward on one side. By increasing the pressure slowly the pharyngoepiglottic ligament can be brought into view in most cases. This structure connects the lateral wall of the hypopharynx with the lateral border of the epiglottis. The superior laryngeal nerve runs about 1 cm. below the free border of this ligament. It is ballooned out by injecting 1 cc. into its pharyngeal root (injection 6). Relaxation of the cricopharyngeal muscle can be achieved by injecting the posterior wall of the hypopharynx just behind the epiglottis. This helps greatly in esophagoscopies (injection 7).

Pharyngolaryngeal Block

Injection No.	Nerve Injected	Site of Injection	Area of Anesthesia	Type of Anesthesia	Dosage, Cc.	Type of Needle	Remarks
1	Superior laryngeal	Hyothyroid ligament	Epiglottis and larynx	Block	3	1 in., 23 gauge	Alternate or supplement to injection 6
2a	Anterior, middle, and posterior palatine	Greater palatine canal	Hard and soft palate, uvula, and anterior pillars	Block	½	Curved tonsillar	Alternate to injection 2b
2b	Middle and posterior palatine	Lesser palatine foramen	Soft palate and anterior pillars	Block	½	Curved tonsillar	Alternate to injection 2a
3	....	Incisive fossa	Upper incisor teeth	Infiltration	0.2	½ in., 26 gauge	Not needed if injection 2a is given
4	Glossopharyngeal	Hilar area of palatinal tonsil	Anterior pillars, tonsil, posterior pillars, and base of tongue	Block	2	Straight tonsillar or 2½ in., 23 gauge	....
5	Terminals of glossopharyngeus	Lingual tonsil	Base of tongue and lingual aspect of epiglottis	Infiltration	2	Curved tonsillar	Supplement to injection 4
6	Superior laryngeal	Pharyngoepiglottic ligament	Epiglottis and larynx	Block	1	Curved tonsillar	Alternate or supplement to injection 1
7	....	Posterior wall of hypopharynx	Hypopharynx and cricopharyngeal muscle	Infiltration	1	Curved tonsillar	For esophagoscopy

It is not necessary to wait between injections. In order to save time, the instillation of the above-described hexylcaine-tripelennamine mixture can be given after injection 1. A dose of 0.25 cc. is administered through the glottis. Another dose should be instilled after all the injections. The entire procedure takes about 12 minutes. *I have named this method pharyngolaryngeal block* (p-l block for short).

SUMMARY

Pharyngolaryngeal block, an anesthetic method for peroral endoscopies, gives a safe and complete (deep) anesthesia.

Seventh Street and Indian School Road.

CAROTID EXPLORATION FOR HEMIPLEGIA FOLLOWING MITRAL VALVE SURGERY

David P. Boyd, M.D., Boston

The incidence of cerebral embolization during th performance of mitral valve surgery has been estimate at 5%.[1] Bailey [2] and his associates have found that the can greatly reduce this incidence by intermittent caroti occlusion during the surgical procedure. It may be tha in the majority of instances cerebral embolization occur in the brain. It had been our assumption that this was s and that nothing could be done about the hemiplegi that occasionally occurs during or shortly after this typ of operation. That this assumption on our part was a least occasionally incorrect is borne out by the followin case report.

REPORT OF A CASE

A woman, aged 39, knew she had rheumatic fever for som years. She never had cardiac decompensation nor was there a history suggesting embolism. Digitalis therapy was used f several years for auricular fibrillation. After careful medic study she was considered to have grade 2 to 3 mitral stenos without major involvement of other valves and without sig nificant mitral insufficiency. Mitral commissurotomy was recom mended. At the time of operation no complications were en countered. Entry into the auricular appendage and into th auricle was carried out without difficulty, and a tight mitra stenosis with calcification was found. There was minimal re gurgitation. No clots were palpable either in the appendage o in the auricle itself. Both anterior and posterior commissura were readily fractured with the finger and an excellent mitra opening was obtained.

The patient was operated on in midafternoon, and in the earl postoperative period, during which time special duty nurses were present, nothing alarming was noted. In the early morning on surgical rounds it was noted that the patient did not respond and that hemiplegia on the right was present. It did not occur to the examiners at that time to palpate her carotid arteries.

From the Department of Surgery, the Lahey Clinic.

1. Bailey, C. P., and others: Commissurotomy for Mitral Stenosis: Technique for Prevention of Cerebral Complications, J. A. M. A. **149**:1085-1091 (July 19) 1952.

2. Bailey, C. P.; Bolton, H. E., and Redondo-Ramirez, H. P.: Surgery of the Mitral Valve, S. Clin. North America **32**: 1807-1848 (Dec.) 195

Consultations with members of the departments of anesthesia and neurosurgery, however, with the idea of performing stellate ganglion block, brought out the fact that the left carotid was not pulsating. The patient was taken to the operating room at once, and with the patient under local anesthesia the left common carotid artery was exposed. Just below the bifurcation the artery was flaccid and soft. A Blalock clamp was applied at this level. An inch or two lower down the artery was fuller and firmer, suggesting an intraluminal clot. A catheter was passed around the proximal carotid artery and a longitudinal incision made in this region. A fresh blood clot immediately protruded and was removed; however, it was not until several additional pieces of clot had been aspirated from the lower common carotid down almost to the aorta that normal hemorrhage from the artery commenced. Back bleeding was profuse from the start. The incision in the vessel was closed with three interrupted silk sutures and the wound closed in layers in the usual manner. A good pulse was felt from this point on in the left superficial temporal artery. Anticoagulant therapy was instituted at once. The patient's cerebral status did not improve, and she died 24 hours after the second operation. Promptly after the second procedure, however, she performed voluntary movements of the right upper and lower extremities and at times seemed able to phonate and react to various stimuli.

COMMENT

It is probable that this carotid embolization or thrombosis occurred during the operation on the mitral valve or very shortly afterward. It is not surprising that after almost 24 hours of total interruption of one side, recovery did not take place. Despite the unfortunate outcome in this case, certain useful principles emerge and should be emphasized. Thus it seems reasonable to recommend that the anesthetist observe the common carotid pulsations frequently throughout the operation for mitral commissurotomy. The fact that thrombosis is not found in the appendage or in the auricle apparently is no guarantee against the development of postoperative thrombosis. In addition, the following specific recommendation is made, namely, that in cases of mitral commissurotomy a type of anesthesia be utilized that will permit the patient to awaken before he leaves the operating room. If hemiplegia is determined to be present, then carotid pulsations should be noted on the appropriate side. If there is the slightest question concerning the presence or absence of this pulsation, the artery should be explored. It may well be that occlusion of the internal carotid artery may occur in some cases at the bifurcation of the common carotid, and, even if pulsations are present in the common carotid and in the superficial temporal arteries, exploration of the carotid arteries should be considered.

SUMMARY AND CONCLUSIONS

Postoperative hemiplegia following operations on the mitral valve may be due to obstruction of the common carotid artery. This complication may also be caused by obstruction of the internal carotid artery at the bifurcation of the common carotid artery. The anesthetist should continually observe pulsations in the carotid arteries during the performance of the surgical procedure. In every case of mitral valvulotomy in which the complication of hemiplegia is demonstrated postoperatively, the carotid artery should be explored. All nurses, residents, and others concerned in the postoperative care of these patients should be thoroughly briefed relative to prompt recognition of this complication.

605 Commonwealth Ave. (15).

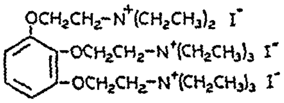
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

R. T. Stormont, M.D., *Secretary.*

Gallamine Triethiodide. — $C_{30}H_{60}I_3N_3O_3$. — M.W. 891.56. — [v-Phenenyltris(oxyethylene)]tris[triethylammonium iodide].—Tri(diethylaminoethoxy)benzene triethyliodide.—The structural formula of gallamine triethiodide may be represented as follows:



Actions and Uses.—Gallamine triethiodide, a synthetic substituted quaternary amine compound similar in action to curare, is useful to relax skeletal muscle for the same purposes and with the same precautions as other curare-like agents. (See New and Nonofficial Remedies 1955, under the general statement on curare.) Unlike curare and its derivatives, gallamine triethiodide exhibits little action on autonomic ganglions. It is useful with general anesthesia to provide more complete muscular relaxation during surgical, manipulative, endoscopic, and intubation procedures. It is also used to prevent accidents during convulsive shock therapy and to reduce muscle spasm during nonoperative orthopedic procedures. Further observations are needed to confirm its usefulness in obstetrics and for the management of convulsions and chronic spastic states secondary to disease.

Like all potent curare-like drugs, gallamine triethiodide should be used only by those thoroughly familiar with such agents and only when facilities for intubation, artificial respiration, oxygen therapy, and administration of antidotes are immediately available.

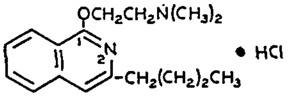
Gallamine triethiodide may produce an allergic reaction in patients sensitive to iodine and care should be taken to avoid severe reactions of this type. The drug is absolutely contraindicated in patients with myasthenia gravis.

Dosage.—Gallamine triethiodide is administered by intravenous injection as an aqueous solution. The dosage should be individualized by careful observation of the patient. The theoretical initial dose is about 1 mg. per kilogram of body weight. For prolonged procedures, additional doses of 0.5 to 1 mg. per kilogram may be injected at intervals of 40 to 50 minutes. Like curare, its action is cumulative.

The drug is readily miscible with solutions of thiopental sodium. In conjunction with ether inhalation anesthesia, smaller doses are required than for other general anesthetics. The same antagonists that are effective against tubocurarine will interrupt the action of gallamine. Neostigmine methylsulfate, 0.5 mg. to 1.5 mg., is a useful antidote and atropine sulfate may be administered simultaneously to counteract the postganglionic effect of neostigmine. A larger dose of the antidote is needed when gallamine is used in conjunction with ether because the latter impedes removal of the drug. Antidotes should be used with caution in asthmatic patients sensitive to such drugs. Such adverse antidotal effect is also counteracted with atropine.

Lederle Laboratories Division, American Cyanamid Company, cooperated by furnishing scientific data to aid in the evaluation of gallamine triethiodide.

Dimethisoquin Hydrochloride. — $C_{17}H_{24}N_2O.HCl$. —M.W. 308.86.—3-Butyl-1-(2-dimethylaminoethoxy) isoquinoline hydrochloride.—The structural formula of dimethisoquin hydrochloride may be represented as follows:



Actions and Uses.—Dimethisoquin hydrochloride, an active surface anesthetic, differs chemically from local anesthetics of the benzoate ester type, such as procaine, and is somewhat more active. Its toxicity is less than that of dibucaine but greater than that of cocaine or procaine. Its index of sensitization is considered to be somewhat less than that of procaine derivatives.

Dimethisoquin hydrochloride is useful topically for the relief of itching, irritation, burning, or pain in a wide variety of dermatoses, including nonspecific pruritus and mild sunburn. Evidence indicates that its effectiveness against pruritus is only about 20% greater than that of the vehicle in which it is applied. It also may reduce the pain of sutured surgical wounds. Because of its apparent lack of systemic toxicity and low index of sensitization when applied to the skin, the drug is considered relatively safe for unsupervised use as a topical remedy for symptomatic relief of simple irritations that may accompany undiagnosed minor skin conditions. When these symptoms persist, the underlying cause should be determined by consultation with a physician. Relief of pruritus also may aid in the treatment of the underlying cause with more specific forms of therapy.

Although dimethisoquin hydrochloride has not been associated with systemic toxicity or sensitivity when applied topically to mucous membranes, its use should be restricted to the skin until there has been longer experience regarding its effects on other tissues. For the same reason it should not be applied to extensive areas of the skin. Contact with the eyes should be avoided to prevent stinging.

Dosage.—Dimethisoquin hydrochloride is applied topically to the skin, either as a 0.5% lotion for moist lesions, or as a 0.5% ointment for dry lesions. Either lotion or ointment is applied as a thin film over the affected area. One application of either form usually provides relief for 2 to 4 hours. Application more than four or five times daily seldom is required. Should sensitization appear after repeated applications, further use should be discontinued.

Smith, Kline & French Laboratories cooperated by furnishing scientifi data to aid in the evaluation of dimethisoquin hydrochloride.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

The Council on Physical Medicine and Rehabilitation has authorized publication of the following article.

RALPH E. DE FOREST, M.D., *Secretary*

FEDERAL COMMUNICATIONS COMMISSION TYPE APPROVAL FOR MEDICAL ULTRASONIC APPARATUS

Fairly recently the Federal Communications Commi sion established new regulations for industrial and me ical ultrasonic apparatus.[1] In an article in THE JOURNA the Council on Physical Medicine and Rehabilitation i formed the medical profession of the intention of th Federal Communications Commission to establish suc regulations.[2] Only data pertinent to the medical profe sion concerning the FCC regulations follow; howeve persons concerned with the technical and precise appl cation of the commission's rules should consult the con plete regulations.

Definition.—Ultrasonic equipment covered by t regulations includes any apparatus that generates rad frequency energy of frequencies above 20 kilocycles p second and utilizes that energy to excite or drive an ele tromechanical transducer for the production and tran mission of ultrasonic energy for industrial, scientifi medical, or other purposes (ISM frequency bands).

Operation Without a License.—Ultrasonic equipme may be operated without a license provided the desig and operation complies with the technical limitations f such equipment and provided that the equipment h been (1) type approved by the commission or (2) ce tificated in accordance with commission requiremen and the certificate attached to the equipment or promi nently posted in the room in which the equipment i being operated. Ultrasonic equipment operating on fre quencies below 90 kilocycles per second and generatin less than 500 watts of radio frequency power may b operated without a license, type approval, or certifica tion, if such equipment complies with all other applicabl provisions of the regulations.

Technical Limitations.—1. Ultrasonic equipment shal be designed and constructed in accordance with goo

---

1. Federal Communications Commission, Title 47—Telecommunication; Part 18—Industrial, Scientific, and Medical Service: Operation of Ultrasonic Equipment, Docket No. 11031; FCC 55-113, Federal Register **20**: 741-743 (Feb. 3) 1955.

2. Ultrasonic Therapy Apparatus and the Federal Communications Commission, report of the Council on Physical Medicine and Rehabilitation, J. A. M. A. **157**: 39 (Jan. 1) 1955.

engineering practice, with sufficient shielding and filtering to provide adequate suppression of emissions on frequencies outside the ISM frequency bands. 2. The fundamental frequency of operation shall fall outside the frequency bands 490 to 510, 2170 to 2194, and 8354 to 8374 kilocycles per second. 3. The varying conditions under which ultrasonic equipment is operated shall not result in radiation exceeding the following limits:

Frequency, Kilocycles/Sec.	Distance, Ft.	Field, μv/M.
Up to and including 490	1,000	$\frac{2400}{F_{kc}}$ *
Over 490 and up to and including 1600	100	$\frac{24000}{F_{kc}}$
Over 1600 exclusive of frequencies in the ISM frequency bands	100	15

---

* Frequency expressed in kilocycles per second.

4. On any frequency above 490 kilocycles, the radio frequency voltage appearing on each power line to the machine shall not exceed 200 μv. On any frequency below 490 kilocycles, the radio frequency voltage appearing on each power line to the machine shall not exceed 1,000 μv.

Type Approval.—Manufacturers of ultrasonic equipment desiring to obtain type approval for their equipment may request permission to submit such equipment to the Federal Communications Commission. To be acceptable for commission type approval, ultrasonic equipment must meet the following requirements: 1. It must comply with the technical limitations for ultrasonic equipment previously listed. 2. The design and construction of the equipment must give reasonable assurance of compliance with the rules for at least five years under normal operation and with average maintenance. 3. The equipment must also comply with additional general rules relative to type approval found in part 2 of the commission's rules.

Identification of Type Approval Equipment.—Equipment for which a certificate of type approval has been issued shall be identified by the insertion of the FCC type approval number on the name plate of the equipment; in addition, the manufacturer shall furnish each user of type approval equipment a certificate setting forth the conditions under which such equipment shall be operated.

Effect of Certificate of Type Approval.—A certificate of type approval issued by the commission constitutes a recognition that, on the basis of the tests made, the equipment appears to be capable of complying with the technical limitations in the commission's rules, provided such equipment is properly installed, maintained, and operated.

Changes in Type Approval Equipment.—No changes whatsoever may be made in ultrasonic equipment for which a certificate of type approval has been issued, except on specific prior approval by the commission.

Withdrawal of Certificate of Type Approval.—A certificate of type approval may be withdrawn by the commission for one of the following reasons: (1) if the type of equipment for which it was issued proves defective in service, (2) if under usual conditions of maintenance and operation such equipment cannot be relied on to meet the conditions set forth for the operation of the type of equipment involved, or (3) if any change whatsoever is made in the construction of equipment sold under the certificate of type approval issued by the commission, without the specific prior approval of the commission.

Certification Attesting Compliance with Rules.—A certification, as distinguished from a type approval certificate, attesting compliance with these rules may be affixed or posted for any ultrasonic equipment. The certification is based on an inspection of the equipment and measurements taken at the place of use after the ultrasonic equipment has been assembled and is ready for operation. This certification may be executed by any engineer skilled in making and interpreting field intensity measurements. The commission may require such an engineer to present proof of his qualifications to make such measurements.

Renewal of Certification.—This certification does not require renewal; however, when the commission has reason to believe that operation of the equipment concerned may be inconsistent with the rules, it may require a new certification based on a new set of measurements.

Interference from Complying Equipment.—In the event of interference to any authorized radio service caused by ultrasonic equipment operated in compliance with the commission's rules, steps to remedy such interference must be taken promptly; however, when interference to receivers arising from direct intermediate frequency pickup by such receivers of the fundamental frequency emission of type approved or certificated ultrasonic equipment operating in compliance with this subpart, this section of the rules does not apply.

Effective Date of New Regulations.—All ultrasonic equipment manufactured on or after July 1, 1955, must comply with the rules. Ultrasonic equipment manufactured prior to July 1, 1955, may be utilized until July 1, 1965; however, it must comply either with the new rules or with the rules for miscellaneous equipment in section 18.31 of the commission's rules, which require that devices be recertified every three years. After July 1, 1965, all such equipment must comply with the new rules.

SUMMARY

The Council is gratified that the Federal Communications Commission has established these regulations for ultrasonic equipment. They should help to minimize the possibility of radio interference caused by the operation of medical ultrasonic equipment. The effect of these regulations is that after July 1, 1955, ultrasonic equipment may be operated if it meets one of the following requirements: 1. The device must be type approved by the commission and bear the FCC type approval number on its name plate. 2. The device must be tested and certified by a competent engineer as meeting these new FCC rules. 3. If the device does not meet the new rules, it must be tested and certified every three years in accordance with the commission's older rules for miscellaneous equipment. In any event the apparatus certified in this way may not be operated after July 1, 1965. Physicians are urged to acquire only FCC type approved ultrasonic equipment in order to obviate the need for recertification and to be reasonably certain that their apparatus does not cause radio interference.

PREMATURE INFANTS

Although there is some dissatisfaction with the grouping of all infants, including those in multiple births, whose birth weight is 2,500 gm. (5.5 lb.) or less as premature infants, this is still the most practical definition. Improved treatment has done much to save the lives of premature infants, but deaths in the first four weeks of life still occur at a high rate in these infants.[1] The greatest hope at present lies in preventing births from occurring prematurely. Every added week of gestation beyond the 28th week means a gain of 4 to 8 oz. (113.4 to 226.8 gm.) for the fetus, and every gain of 8 oz. cuts the expected death rate in half. The obstetrician can, therefore, do much to prevent prematurity by delaying delivery in patients who have not reached full term and by vigorous treatment of conditions that threaten to terminate pregnancy prematurely. It has been found that the causes of neonatal deaths are the same for premature and full-term infants. These include postnatal asphyxia and atelectasis, birth trauma, congenital malformations, infection, and blood dyscrasias. In the premature infants, however, the death rate from all these causes is higher than in the full-term infants and the proportionate distribution is different. Clifford[1] cites Burke's earlier findings in a series of 284 women. In this group all of the stillbirths, all but one of the neonatal deaths, and all but one of the premature births involved mothers whose prenatal diets were poor, especially in proteins. Clifford then cites Tompkins, who gave 750 expectant mothers a high-protein, high-vitamin, high-mineral diet with a limited intake of fluids and juicy fruits. None of the infants in this group were born prematurely, but in a similar group not on such a diet there were 37 premature infants. A correlation has been found to exist between the deficiency of the diet and the degree of prematurity. Although an inadequate diet is not the only cause of prematurity, it appears to be one of the most important and one that is frequently preventable. Crosse[2] conducted a follow-up study to determine to what extent premature babies later became a burden
to the community through excessive hospitalizatio
unfitness for military service, retarded mental develo
ment, or crime and drunkenness. A higher incidence
congenital defects has been observed in premature i
fants, but this is believed to be the cause of their pr
maturity and not a result of it. The development of a
premature baby depends on the cause and degree of i
prematurity; the presence or absence of complicatio
in pregnancy, labor, and the neonatal period; the quali
of the obstetric and neonatal care; and the parents' phy
ical and economic status. The author concluded th
prematurity per se did not cause future dependency.

The principles of treatment of the premature infa
include prevention of infection, maintenance of respi
tion and body temperature, and proper feeding, pref
ably with human milk.[3] Kagan and his co-workers[4] co
pared the weight gain in groups of premature babies f
on (1) manually expressed human milk; (2) human mi
with skimmed, cultured cow's milk added; (3) co
milk with the proportions of proteins, fats, and lacto
modified to simulate those found in human milk; and (
a half-skimmed cow's milk with added carbohydrates
high in protein and ash and low in fat. All groups we
given the same number of calories per unit of bo
weight. Those in group 4 made the greatest gains
weight, but, because this group got four times as mu
ash per unit of body weight as groups 1 and 2 and tw
as much as group 3, it is believed that the difference
weight gain depended on this difference in ash inta
with ash retention and consequent water retention. T
retention of ash was believed to indicate poor renal fu
tion in the premature babies, and the authors conclud
that weight gain in itself is not a good index of progr
in premature infants in the neonatal period.

In Chicago in 1922 a special premature service w
established at the Michael Reese Hospital. Although
growth was slow, its value became abundantly evide
and in 1932 the small premature service at the C
County Hospital was enlarged. In 1934 with the coop
ation of these two hospitals the Chicago Board of Hea
inaugurated a city-wide plan for the care of premat
infants.[5] It became mandatory that the board of hea
be notified by telephone within one hour of the birth
all premature babies, and unless the baby was in criti
condition transfer to one of the premature units was
ranged. The board of health provided a specia
equipped and staffed ambulance for this purpose. If t
baby was in critical condition, whether at home or in
hospital, an incubator was used, and if none was imme
ately available one was supplied on loan by the board
health. If the baby was at home a specially trained nu
was also supplied, and arrangements were made to tra
fer the baby to a premature unit within the first 24 hou
of life. The board of health also maintained a brea
milk service and impressed on the parents of all prem
ture babies the importance of follow-up care in an ou
patient clinic after the baby was discharged from t
hospital. Similar programs have been established in ma
other large cities. Thus with an increased understandi
of the causes of prematurity and the needs of the prem
ture infant much can now be done to prevent prematu
birth and to save those who in spite of preventive mea
ures are born with a subnormal birth weight.

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Federal Advisory Council on Health

Senator Smith (R., N. J.), in S. 2405, Senator McCarthy (R., Wis.), in S. 2484, Congresswoman Church (R., Ill.), in H. R. 7345, and Congressman Frelinghuysen (R., N. J.), in H. R. 7532, have introduced identical measures to carry out the recommendations of the Commission on Organization of the Executive Branch of the Government (Hoover commission) to establish a permanent federal advisory council of health in the office of the President. The council appointed by the President would be composed of members of the medical profession and "persons with distinguished records in fields other than medicine." Blank spaces were left to be filled in the bill to specify the number of members of the two groups.

The functions of the council, most of which were recommended by the Hoover task forces, would be to: first, "Make a continuous evaluation of and recommendations as to policies and programs relating to Federal medical care and national health. Second. Advise on measures to assure adequate health manpower and hospital facilities for the Nation's health. Third. Review the various proposals and programs relating to hospital construction involving Federal funds, including Federal grants. Fourth. Advise with respect to the coordination of regional hospital services of all departments and agencies in the executive branch of the Government. Fifth. Advise with respect to more systematic cross-servicing between the various Federal medical agencies. Sixth. Advise upon measures for the adequate training and selection of the medical staffs of all Federal Services. Seventh. Advise the executive departments and agencies on all Federal medical policies and programs. Eighth. Advise the Selective Service System on the mobilization of medical personnel. Ninth. Advise concerning systems of project grants for health research programs of the Federal Government. Tenth. Report periodically to the President and to the executive departments and agencies involved on the success or failure of Federal health programs and policies. Eleventh. Report to the President and advise the Bureau of the Budget and the Congress with respect to such matters as they may request. Twelfth. Assist the Secretary of Defense to develop recommendations for revision of the Selective Service Act, as amended, so as to effect maximum utilization of medical personnel. Thirteenth. Advise the Administrator of the Veterans' Administration with respect to recommendations for closing certain hospitals belonging to such administration. Fourteenth. Review the manner in which the hospital facilities of the Veterans' Administration are being used and make recommendations for the disposal of more economic utilization of such facilities. Fifteenth. Advise the President, or any committee established or designated by him, with respect to the policies, programs and operations of the Food and Drug Administration and the Agricultural Research Service in the Department of Agriculture, with a view to eliminating those which are no longer necessary under present conditions and eliminating conflicts and overlapping of jurisdiction and functions between departments. Sixteenth. Make recommendation to improve preventive health services, including those rendered in connection with medical care of Federal beneficiaries, in the interests of both health conservation and long-range economy. Seventeenth. Review and make recommendations to the President with respect to the health research programs of the Federal Government. Eighteenth. Examine the means of establishing cooperative planning among the Federal agencies which provide psychiatric care. Nineteenth. Serve as consultant to the President's advisor on personnel with respect to making more uniform the personnel systems of the several Federal agencies using health personnel." The Senate measures were referred to the Committee on Labor and Public Welfare, the House measures to the Committee on Interstate and Foreign Commerce.

Military Status for Public Health Service

Senator Hill (D., Ala.), in S. 2587, and Congressman Priest (D., Tenn.), in H. R. 7600, would authorize the President to make the commissioned corps of the Public Health Service a military service in time of emergency involving the national defense. Under the present law the commissioned corps may have military status only in time of war. The proposed bills would authorize a one-time uniform allowance of $250 to officers in the lower ranks if the officer is required at any time by the surgeon general to wear a uniform. Under the present law the uniform allowance is effective only in time of war. Technical amendments to the Public Health Service Act would also be made, including retirement benefits, disability benefits, and credit for noncommissioned service. The Senate bill was referred to the Committee on Labor and Public Welfare, which reported it favorably without hearings, and it was passed by the Senate. The House bill was referred to the Committee on Interstate and Foreign Commerce.

Increased Earnings Under Social Security

Senator Smathers (D., Fla.), in S. 2513, would amend the Social Security Act to increase from $1,200 to $1,500 the amount individuals would be permitted to earn without deductions from their benefits upon retirement at 65 years of age. Under the present law, one month's benefits is lost for each $80 earned in excess of $1,200. The limit on earnings applies only to wages and salaries and does not apply to income from life insurance and annuities, pension plans, interest on bonds and savings, dividends from securities, or income from the use of capital investment. This measure was referred to the Finance Committee.

From the Washington Office of the American Medical Association.

Income Tax Deduction

Senator Humphrey (D., Minn.), in S. 2588, would amend the Internal Revenue Code "so as to allow a deduction for certain expenses incurred by a taxpayer for the care of his children while his wife is physically or mentally incapable of caring for such children . . . but only if such care is for the purpose of enabling the taxpayer to be gainfully employed." This measure was referred to the Finance Committee. Congressman Keogh (D., N. Y.) proposes, in H. R. 7602, for income tax purposes to allow for deductions for gifts to nonprofit voluntary health insurance plans before payment of income, gift, or estate taxes. This measure was referred to the Committee on Ways and Means.

Hospital Loans or Grants

Senator Clements (D., Ky.), in S. 2640, would revise and extend the authority of the Housing and Home Finance Administrator to make loans and grants to public and nonprofit agencies for construction of hospitals whose applications prior to June 30, 1953, were denied solely because of the unavailability of funds for such purpose. The authority would expire June 30, 1957. There would be authorized 5 million dollars for each fiscal year, ending June 30, 1956, and June 30, 1957. The bill was referred to the Committee on Banking and Currency.

Mentally Ill of Alaska

Senator Jackson (D., Wash.), in S. 2518, has introduced measures identical to H. R. 6334 and H. R. 6376, previously reported in THE JOURNAL, June 25, 1955, page 665. These measures would modernize the hospitals and commitment procedures for the mentally ill of Alaska and transfer from the federal government to the Territory of Alaska the responsibility and authority for hospital care and treatment of the mentally ill of Alaska. This measure was referred to the Committee on Interior and Insular Affairs.

Death Penalty for Narcotic Sale to Minors

Congressman Latham (R., N. Y.), in H. R. 6921, would make "the sale of narcotics drugs to a minor . . . a criminal offense punishable by death . . . if the drug has been shipped, transported, or carried in interstate commerce." This measure was referred to the Committee on Judiciary.

Food for Hill-Burton Hospital Patients

Congressman Rains (D., Ala.), in H. R. 7621, proposes "to provide for grants to State health agencies to assist Hill-Burton hospitals in providing food for the patients." This measure was referred to the Interstate and Foreign Commerce Committee.

Social Security for Dentists and Lawyers

Senator Langer (R., N. D.), in S. 2751, proposes to amend the Social Security Act to provide for voluntary coverage of lawyers and dentists under the Federal Old-Age and Survivors Insurance system. This measure was referred to the Committee on Finance.

Atomic Fall-Out

Senator Green (D., R. I.), in S. Res. 134, would endorse the "efforts of our chief delegate to the United Nations to take appropriate steps to work to establish within the United Nations procedures to receive, assemble, and report on radiological information collected by the various states with particular emphasis on radiation effects on human health and safety." This measure was referred to the Committee on Foreign Relations, favorably reported, and passed by the Senate.

Income Deductions for Contributions to Nonprofit Voluntary Health Insurance Plans

Senators Flanders (R., Vt.), Ives (R., N. Y.), and Lehman (D., N. Y.), in S. 2700, have introduced an identical measure with H. R. 7602, previously reported. In this measure they propose to allow income tax deductions for gifts to voluntary health insurance plans in calculating federal income tax. This bill was referred to the Committee on Finance.

Commission for Programs for the Aging

Congressman Ostertag (R., N. Y.), in H. R. 7499, would establish a 12-member fact-finding commission on problems of the aging, including (*a*) physical and mental aspects, (*b*) employment, (*c*) retirement programs, (*d*) housing, and (*e*) recreation. This bill was referred to the Committee on Education and Labor.

COMMISSION ON ACCREDITATION OF HOSPITALS

Dr. E. Vincent Askey, Speaker of the A. M. A. House of Delegates, has appointed a seven-man special committee to review the function of the Joint Commission on Accreditation of Hospitals. Letters of invitation to serve on the committee have been sent to Drs. W. C. Stover, Boonville, Ind., chairman; John F. Burton, Oklahoma City; Gerald D. Dorman, New York; George F. Gsell, Wichita, Kan.; Eugene F. Hoffman, Los Angeles; T. C. Terrell, Fort Worth, Texas; and George A. Unfug, Pueblo, Colo. The committee was appointed as the outgrowth of the introduction of six resolutions in the House of Delegates at the A. M. A. session in Atlantic City in June, 1955. Dr. Askey hopes that the committee will be able to submit some kind of a report to the House when it meets in Chicago next June.

HEALTH TIPS FOR TV AUDIENCES

Before the doctor comes, "what to do" about a sore back, dizzy spells, or blotches on the skin is a familiar cry in every household. To help mother cope with such emergencies, the American Medical Association now presents the third series of six five-minute films entitled, "What To Do." Featuring Actress Abby Lewis, this series presents authentic health information on eye injury, backache, baseball finger, dizziness, hay fever, and skin problems. Series 3 now is available from the A. M. A.'s film library for use by local medical societies over local television stations.

BUREAU OF MEDICAL ECONOMIC RESEARCH

This is the second and concluding part of the survey on the economic position of medical care during a quarter of century. The first part appeared in THE JOURNAL, *Sept. 3, page 41.*—ED.

THE ECONOMIC POSITION OF MEDICAL CARE, 1929-1953

Frank G. Dickinson, Ph.D.
and
James Raymond, M.A., Chicago

Medical Care Prices

Measurements of the changes in the level of medical care prices during this quarter century cannot be presented in the same manner as the changes in personal consumer expenditures for medical care. First, index numbers measuring changes in medical care prices were not developed by the United States Bureau of Labor Statistics for the first six years of this quarter century. Its so-called cost-of-living indexes for the six years 1929 to 1934 (on the basis of 1935-1939 average prices) were: 122.5, 119.4, 108.7, 97.6, 92.4, and 95.7; but no indexes were computed and published for medical care prices. As a partial offset for these missing price indexes for the first six years we have chosen to discuss medical care prices in 1954, although the last year in the personal consumer expenditure series was 1953. Second, a complication arises from the decision of the Bureau of Labor Statistics several years ago to abandon the 1935-1939 base and substitute the 1947-1949 base. Fortunately, this decision has been altered somewhat and some indexes on the old base period are still being compiled and published. Although these will be featured in our discussion of medical care prices, it will be necessary to make comparisons of old base and new base indexes for a number of items. Third, changes in the major classifications, that is, in the columns published each month in the appendix section of the *Monthly Labor Review* of the United States Department of Labor in the new base Consumer Price Index also complicate comparisons with the old base indexes. The number of major items (columns in the tables published monthly) has been increased from 9 to 13, but both the old and the new present separate indexes for 6 items: food, apparel, rent, gas and electricity, fuel, and house furnishings. There were also old base indexes for three items: fuels, electricity, and refrigeration (a grouping of three items), ice, and miscellaneous (such items as medical care, transportation, recreation, household operation, and personal care). There are also new base indexes for seven items: housing (a grouping of five of these major items), household operation, transportation, medical care, personal care, reading and recreation, and other goods and services. Because we must discuss both the old and the new base indexes, we shall use the term "indexes" to refer to these major categories whether they are in both sets of indexes or in only one, and the term "subindexes" for those indexes that are not, or were not, published monthly.

The Consumer Price Index, as it is now called, springs from a rather long line of efforts by the Bureau of Labor Statistics to measure changes in the level—not the level itself—of prices paid for many commodities and services by city consumers of moderate incomes. Retail prices of representative commodities and services are sampled monthly or quarterly in a number of retail outlets in selected cities in the United States. These sample prices are then used by the members of the staff to compute the monthly, quarterly, or annual indexes. Rather than paraphrase the description of the present Consumer Price Index given by the Bureau of Labor Statistics, we prefer to quote rather lengthy excerpts:

"The Consumer Price Index of the Bureau of Labor Statistics is a statistical measure of changes in prices of the goods and services bought by families of city wage earners and clerical workers. . . . A complete name for this index is: *'Index of Change in Prices of Goods and Services Purchased by City Wage-Earner and Clerical-Worker Families to Maintain Their Level of Living.'* It is referred to as 'The Consumer Price Index.' However, the long title contains the key to the meaning of the index.

"The index is concerned with *prices*. These are the retail prices of foods, clothing, housefurnishings, fuel and other goods; the fees paid to doctors and dentists; prices in barber shops and other service establishments; rents; rates charged for transportation, electricity, gas and other utilities; and so on. They are prices charged to consumers, including sales and excise taxes . . . urban wage-earner and clerical-worker families . . . are families of two or more persons living in the 3000 towns, cities and suburbs of the United States, ranging in population from small cities of 2500 people to New York City. . . . The average size in 1952 of the families included in the index was estimated to be about 3.3 persons, and their average family income was estimated at about $4160 after taxes. . . .

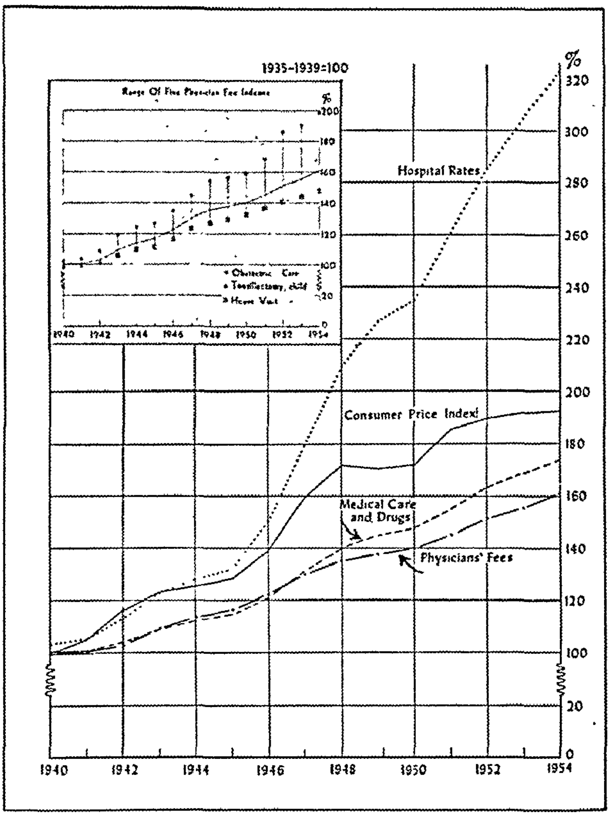

Chart V.—Consumer Price Index and medical care indexes, 1940-1954. Source: U. S. Bureau of Labor Statistics.

"The 'index market basket' is an estimate of the goods and services bought by this group of the population in 1952 to use, replace and add to their possessions, to keep up their 1952 level of living . . . the 'index market basket' does not reflect purchases of families at the lowest and highest extremes of the income scale, who live at different levels of living.

"The index is concerned with *change* in prices. It measures the effect of price changes on the cost of the goods and services in the 'market basket.' The content of the 'market basket'—that is, the quantities and qualities of goods and services that represent what families bought in 1952—is assumed to remain the same, so that the change in cost from month to month is the result of *changes in prices*. . . .

Director (Dr. Dickinson) and Staff Associate (Mr. Raymond), Bureau of Medical Economic Research, American Medical Association.

Regina Evans Holloman, research assistant, assisted in the preparation of the tables.

Because of space limitations the appendix has been omitted and will appear in the Bureau's reprints.

"Price changes are expressed in *percentage* terms, and the percent changes for various goods and services averaged and compared to some past period. . . . Thus, if we take the cost of the 'market basket' at the earlier reference date as equal to 100, the index for the later date measures, in percentage terms, how much the cost of the same 'market basket' has changed. An index of 110 means a 10 percent increase; an index of 90 means a 10 percent decrease.

"Index numbers are published by the Bureau of Labor Statistics to one decimal place. The index number of 100.0 is for the average of three years—1947, 1948, and 1949—the 'base period' of the index. Index numbers as published from month to month compare prices *at each date* with the average level of prices in these three years. . . .

"Even though American families buy thousands of different kinds and qualities of variously priced goods and services, prices of many groups of items change at about the same rate . . . so that a change in the price of one . . . may be representative of the others. . . .

"In 1950 and 1951 the Bureau priced and studied the price changes of hundreds of items [and] . . . selected about 300 items, which together can be used to estimate the average change in prices of all items. . . . It is important to be certain, however, that the calculation shows *only* price change and not changes due to other things, such as quantity or quality differences. . . . To prevent this, insofar as possible, the Bureau has prepared detailed specifications to describe the items that are priced for the index. . . ."[3]

Indexes for the years prior to 1953 were computed on the old base period. The price data were collected by this sampling process in 34 large cities only one of which had a population of less than 100,000 in 1950. Food and fuels were priced monthly in all of these cities, and other commodities and services were priced on varying cycles. Only in the five largest cities was the complete list sampled each month. According to Bulletin 1165 of the Bureau of Labor Statistics, the old base subindexes used in our tables for the years prior to 1953 were based on prices collected in the following 18 cities: Baltimore; Birmingham, Ala.; Boston; Chicago; Cincinnati; Detroit; Houston, Texas; Jacksonville, Fla.; Los Angeles; Memphis, Tenn.; Minneapolis, Minn.; Mobile, Ala.; New York; Philadelphia; Pittsburgh; Portland, Maine; St. Louis; and San Francisco. Prices for the new base indexes were collected monthly for food, fuel, and rent in 46 cities. But the old base subindexes for 1953 and 1954 presented in our tables (that is, all of the components of the medical care and drugs index, furniture, men's street shoes, women's cotton house dresses, and motion picture admissions) were compiled quarterly from prices collected in only 14 cities with a total population of about two-fifths of the population of the 46 cities. The 14 cities are: Atlanta, Ga.; Baltimore; Chicago; Cincinnati; Detroit; Los Angeles; Madison, Wis.; Newark, Ohio; New York; Philadelphia; St. Louis; San Francisco; San Jose, Calif.; and Youngstown, Ohio. In order to present subindexes (table 6) for the 20 categories under medical care and drugs for 1953 and 1954 it has been necessary for us to utilize subindexes based upon only 14 cities and computed on the old base period, which we prefer. It is not impossible, however, that the data for the 14 cities reveal the changes in prices as well as would have data from either the 18 or the 46 cities. Certainly this narrower base qualifies our analysis. The omission of these 20 subindexes would restrict the discussion to the new base period without any subindexes under medical care and drugs.

TABLE 6.—*Consumer Price Index, Index and Subindexes for Medical Care and Drugs, 1940-1954*
1935-1939=100.0

* December, 1950 = 100.0.

Beginning in January, 1953, the Bureau of Labor Statistics shifted over to the new base, 1947-1949. Other important changes that were put into effect were discussed in our Bureau Bulletin 95, "Old and New Base Periods for Medical Care Price Indexes"; we analyzed in some detail the effects of shifting from the old base to the new base. The objections made to the change in base periods were: (1) the changes were made during an inflationary period, (2) the years chosen as the new base period (1947-1949) were themselves inflationary years, (3) the selection of these years assumed, unjustifiably, that most of the components of the Consumer Price Index reflected the inflationary trend to approximately the same extent, (4) the selection of these particular years also assumed, again unjustifiably, that substantially all the post-World War II readjustments in prices had occurred prior to Jan. 1, 1947. A brief examination of one of the major components of the total Index, rent, will demonstrate the last two objections. Rents could not have kept pace with other inflationary trends because rents were still subject to the controls imposed during wartime, and rents were not decontrolled until the fall of 1953, well after the close of the new base period. That the postwar years through the end of 1951 were inflationary years is shown clearly by chart V. The Consumer Price Index, based on the 1935-1939 average, rose steeply each year from 1945 to 1951, from 128.4 to 185.6. Its rate of climb began to diminish late in 1951; as may be seen from the even numbered columns of table 6 and in chart V, the Consumer Price Index rose only 1.5 points from 1952 to 1953. In 1953 the Index was 191.3, and by 1954 it was 191.9, i. e., it had climbed scarcely more than ⅓ point during 1954. (For the first quarter of 1955, it was 191.1.) This indicates that since 1951 the consumer price level was stable.

---

[3] The Consumer Price Index: A Short Description of the Index as Revised, 1953, United States Department of Labor, Bureau of Labor Statistics, January, 1953.

Bulletin 95 also cited some of the desirable changes in the revised Index: 1. The "index market basket" was enlarged so that about 300 items are now being priced as compared with about 200 items for the old base index. 2. The contents of this index market basket were modernized; e. g., penicillin was substituted for quinine and the price of home maintenance was obtained for the first time. 3. The major groups were increased from six to eight. 4. The method of assigning a weight to each item priced was changed so as to utilize 1950 population data rather than data from the 1940 census. 5. The number of cities where prices were sampled was increased from 34 to 46. This larger number of cities is more nearly representative of the distribution of all United States consumers than was the former list of 34 large cities. Our conclusion was that if indexes were not presented by the Bureau of Labor Statistics for both the old (1935-1939 = 100) and the new (1947-1949 = 100) base periods, an illusory effect might be created for such components of the Consumer Price Index as rent and medical care. As noted, the Bureau of Labor Statistics has decided to continue to provide some indexes on the old base. These old base subindexes (for the 20 categories under medical care and drugs and other categories) for 1953 and later are not published monthly in the *Monthly Labor Review* but, instead, in occasional publications of the Bureau of Labor Statistics; as noted, subindexes based on the 1935-1939 averages frequently do not have as broad a samplying base as do the regularly published indexes based on the 1947-1949 averages. The annual old base indexes and subindexes for the years since 1949 are presented in the last five columns of table 6 [and in the even-numbered columns, except (2) of table 7].

The years 1935-1939 constitute a better base period than the years 1947-1949. Our major emphasis is, therefore, placed on the "old base" indexes; some are presented in chart V. Moreover, more subindexes of the eight major groupings have actually been published by the Bureau of Labor Statistics on the old base than on the new base. Item indexes based on 1947-1949 = 100 are, however, provided here for the reader who desires to make comparisons; those new base subindexes not made available by the Bureau of Labor Statistics have been calculated—the odd numbered columns of table 7 and the bottom four rows of table 8. Where this has occurred in tables 7 and 8, entries will be found in table columns headed "Conversion Factor"; otherwise, all price indexes appearing in this bulletin are those published or furnished by the Bureau of Labor Statistics.

Table 8 shows indexes for both the 1935-1939 and 1947-1949 base periods for selected commodities and services. Indexes and subindexes for the year 1954, columns (12) and (13), showing the end-results of the shift in base periods, reveal three patterns: (1) individual indexes that were higher than the entire Consumer Price Index on the old base, 191.9, and become lower (than 114.8) on the new, (2) indexes that were lower than the entire Consumer Price Index on the old base and became higher on the new and, (3) those indexes that were high or low on both periods. These patterns reflect the differences in price movements before and after 1947-1949. The food index reflects the first pattern; on the old base, the 1954 index for food, 227.5, was considerably above the entire Consumer Price Index, 191.9, but on the new base it was below it, 112.6 versus 114.8. This means that food prices increased greatly prior to 1947-1949 but have risen less rapidly than prices for other items since that time. Price indexes for personal care, as well as the subindexes for furniture and women's cotton house dresses, reflect the same pattern as food; the prices of women's cotton house dresses in 1954 were sharply misrepresented by the shift in base period —276.1 versus 94.7. The 1954 indexes for medical care and drugs on the old and the new base periods show the second pattern. They are lower than the entire Consumer Price Index on the old base, 173.9 versus 191.9, and higher on the new base, 125.2 versus 114.8. The price indexes for rent and transportation also follow this second pattern in which the new base indexes suggest high levels of prices in 1954 because the prices lagged so much before 1947-1949 and subsequently rose relatively fast. While price increases for these items were rapid after 1947-1949—serving to bring these prices into line with those for commodities and services that had accelerated earlier—their

increase over the entire period, 1935-1954, has not been as great as that for the entire Consumer Price Index.

For the remaining items, D to G, in table 8 the shift in the base period does not change the rank order. The index for reading and recreation was lower than the entire Consumer Price Index on both bases, while the subindex for motion picture admissions was slightly higher on both. Although the subindex for men's street shoes was higher on both bases, it was so much higher on the old base (268.4 versus 191.9) than on the new base (119.7 versus 114.8) that the misrepresentation of the 1954 new base subindex is almost as great as that for women's cotton house dresses. If it had been possible and feasible for the Bureau of Labor Statistics to present price quotations in dollars and cents along with price indexes and subindexes for each year since 1935, the mirage of favorable prices to consumers in 1954 for food, personal care, furniture, women's cotton house dresses (and men's street shoes) and unfavorable prices for rent, transportation and medical care would disappear; in fact, the reverse would be evident.

The stability of the entire Consumer Price Index during 1952-1954, when it moved so narrowly from 189.8 to 191.3 to 191.9, suggests that this later period would outrank 1947-1949—when the Index jumped from 159.6 to 171.9 and 170.2—as a good choice for a post-World War II base period. Having criticized the undue haste in selecting 1947-1949 as a base period, we are now bold enough to suggest that it be quickly abandoned in favor of 1952-1954; the latter approaches the stature of a "normal period."

SUBINDEXES FOR MEDICAL CARE

The subindex for physicians' fees has been consistently lower than that for the broader subindex, medical care excluding drugs. In 1954 the subindex for medical care excluding drugs was 182.6 (table 6), while that for physicians' fees was 160.3—22.3 points lower. The subindex for physicians' fees was computed from a sample of general practitioners' fees for office (163.5) and house visits (148.8) and obstetric cases (198.0) in certain cities; and by pricing surgeons' and specialists' fees for performing appendectomies in adults (151.4) and tonsillectomies in children (160.0). The increases in the subindexes for physicians' fees are fairly similar, except for the obstetric case. As indicated in the inset in the upper left-hand corner of chart V, there is an ever-widening spread since 1943 between the lowest subindex, house visit, and the highest subindex, obstetric case. (We have been unable to find conclusive evidence that a portion of the rise in this subindex has resulted from a measurable increase since 1935 in the quantity of physicians' services given in an obstetric case.) The forces of supply and demand being what they are, it is perhaps surprising that the great increase in number of babies born in 1953 over the number born in 1945 has *not resulted in an even greater post-World War II increase in* these subindexes, particularly for obstetric care; in 1945 there were 2,700,000 births as compared with 3,900,000 in 1953.

The subindexes for dentists' fees rose 3.3 points from 1951 to 1952, 5.5 points from 1952 to 1953, and 5.7 points from 1953 to 1954. The average of the four quarterly indexes for dentists' fees for 1954 was 174.5; the subindexes for dental extractions show, however, more rapid and marked increases. The subindexes for hospital room rates have continued their disproportionately rapid rate of increase. The 1954 subindex for hospital room rates was 322.1, that is, hospital room rates apparently were 222% higher in 1954 than in 1935-1939. Moreover, the 1954 subindex is 130 points higher than the Consumer Price Index, 148 points higher than the medical care and drug index, and 162 points higher than the subindex for physicians' fees. The indexes for medical care and drugs would have been markedly lower if the component subindexes for hospital room rates had not skyrocketed. This subindex reflects only changes in room rates, not changes in the unit prices of laboratory and other "extra" services that the attending physician orders for his patient. Population increase and especially the big baby crop of the postwar years have, together with health education, increased greatly the demands for hospital care. In 1929 only 29% of the United States births occurred in registered hospitals, but in 1953 the percentage was 85; and, in some states, the percentage was as high as 98. The subindex of 132.2 for prescriptions and drugs, as a whole, shows the least increase of any grouping in table 6; the 1954 subindex for prescriptions alone was 152.4, and its course in the 1950's is parallel to the course of the subindex for surgeons' and specialists' fees for appendectomies performed on adults.

NEW BASE INDEXES

The purpose of table 7 is to provide a counterpart to the missing breakdowns for medical care items on the new base period, 1947-1949. One general conclusion may be drawn from a perusal of this table: Even on the old base, the rate of increase in the index for medical care and drugs, as well as for one of its chief components, physicians' fees, has been more rapid in recent years than for the entire Index. Readers of current Department of Labor publications and monthly press releases, seeing only the new base indexes for the entire Index and for medical care and drugs (the first two rows of the odd numbered columns of table 7) in the published tables, will note that the medical care index is rising at a faster rate than the entire Index, but readers will not see the sharply rising subindexes for hospital rates, a subindex that has risen far faster than the other subindexes of medical care. They may very well conclude that the upward change in every component of medical care prices is relatively greater than upward changes in prices for all consumer goods and services. Most important, they will not have before them the old base subindexes indicating that other medical care prices continue to be quite reasonable.

The first two rows of table 7 on the new base are published monthly and are given wide publicity in the press. We have used the published breakdowns (table 6) of the medical care items on the old base and a conversion factor to obtain "conversion subindexes" on the new base. The conversion factor is the reciprocal (multiplied by 100) of the averages for 1947-1949 of the old base subindexes; there is one conversion factor for each subindex. These conversion factors were then applied to the old base subindexes for each year since 1949 to obtain the conversion subindexes on the new base. This procedure does not, of course, increase the number of cities in the sample from 14 or 18 to 34 or 46 in the computed new base subindexes. In that sense these computed new base subindexes in the odd-numbered columns of table 7 do not have the sampling coverage of the medical care and drug index on the new base published each month. They provide, in a sense, a second basis—in addition to table 6—for watching the behavior of the subcategories of medical care and drugs on the new base during the period, 1950 to 1954, and directly comparing each with the entire Consumer Price Index and the index of medical care and drugs. Similar comparisons for years after 1949 can be made from table 6.

The 1954 subindex for physicians' fees, 119.1, was above the entire (new base) Consumer Price Index of 114.8 [column (13), table 7]. The 1954 subindex for general practitioners' fees was 119.9 and for surgeons' and specialists' fees, 115.1. The latter was very close to the entire Consumer Price Index for 1954, 114.8. The principal reason why the subindex for general practitioners' fees was 5.1 points higher is, of course, the rise in fees for obstetric case; this subindex was 131.3 in 1954, the only really moderately high subindex among the seven for physicians' fees. The upward tug of fees for obstetric care is indicated in the inset in chart V for all the years since 1939. The subindex for hospital room rates was 156.9 for 1954. Again, it is this part of the medical care and drugs index that is mainly responsible for the 1954 new base index of medical care and drugs being over 10 points above the entire Consumer Price Index, 125.2 versus 114.8. Finally, the 1954 subindex for prescriptions and drugs was only 110.1; this item is, of course, a commodity and not a service, and the American genius for efficient mass production is among the factors responsible for keeping drug prices and, in turn, their price subindexes low. Indeed, it is unfortunate that some genius at mass production cannot put hospital rooms, therapy, and nurses on an assembly line and invent a machine able to give a patient after operation a bath and handle several tubular appendages to take care of such necessities as drainage and injections. The chores incident to getting sick people well must still be carried out by artful human hands. The shorter work week, the severe competition of other job opportunities, and similar factors have continued to push upward the nursing and other labor costs of operating a hospital—almost two employees are needed per patient. Unlike physicians and dentists, the hospital is an institution, and the services that it sells are produced by individuals with equipment, food, and supplies. Some of these were still in the inflationary spiral in 1954, with no end in sight. Fortunately the average length of stay of patients continues to decline.

This discussion of new base indexes and subindexes and our use of a conversion factor on the old base subindexes to develop new base subindexes for the categories of medical care and drugs should not obscure our argument against the new base itself. The new base period was a period of rising prices in the United States rather than a "normal" period. The suppliers of those goods and services that had risen rapidly in price by 1947-1949 may prefer to use the new base period solely because it makes their product or service seem low in price regardless of the current dollar price and regardless of any general consideration of the merits of choosing a postwar inflationary period for a base for this very important Index. Insofar as the Bureau of Labor Statistics measures changes in the levels of prices of medical care and drugs, we are entitled to state that, with the exception of hospital room rates, no medical care subindex has risen as rapidly as the Consumer Price Index since 1935-1939. On the other hand, we have frankly admitted that the subindexes for physicians' fees, notably for an obstetric case, have risen more rapidly since 1947-1949 than has the entire Consumer Price Index. As time passes, the monthly reports of changes in these indexes may well obscure the facts for the longer period of time, 1935-1954. Every student of economics is confronted with choices of periods of time to study. We have set forth the conclusions based upon these two intervals of time, one long and one short, and stated a strong preference for the longer period.

Changes in Efficiency and Incomes

One established method of estimating the volume of production is to divide an index of dollar sales or purchases by a suitable index of prices. This procedure is sometimes called "deflation of a dollar series" and the result, a "constant price series." This division is designed to eliminate the effect of changes in prices. In using the indexes of personal consumer expenditures in table 4 and the indexes of consumer prices of table 6 for the same items, it should be remembered that these two series do not completely match. One series is published by the Department of Commerce for its purposes and the other series by the Department of Labor for its purposes. Nevertheless, the two fit about as well as most pairs of indexes of dollars spent and prices paid. Setting the ratio between the two indexes equal to 1.0 in the old base period, 1935-1939, we note that the index of personal consumer expenditures in 1947-1949 was 274 as compared with the Consumer Price Index of 167, thereby establishing a production index of 1.6 for 1947-1949; it was 1.8 in 1950 and 1.9 in 1953.

The production ratio for medical care alone was 2.0 (281 divided by 139) in 1947-1949; it was 2.2 in 1950 and 2.3 in 1953. (A production ratio cannot be presented at this time for 1954 because the data for computing the index for the numerator, total personal consumer expenditures for medical care, has not been reported.) The 1953 production ratio for physicians' services was 2.2 (343 divided by 156), for dentists' services 1.6, and for hospitals 1.9. The data in the various tables permit computations of other production ratios. The 1953 production ratios for physicians and dentists indicate a gross increase in the amount of their services consumed by the people, especially physicians' services. Considering the increase in the number of physicians and dentists since the base period and other qualifying factors, this procedure indicates an increase of more than 69% in the output per physicians and more than 33% in the output per dentist. Moreover, since the population of the United States increased only 23% between 1935-1939 and 1953, it follows that there has been a marked increase in the consumption of medical services per capita, possibly as much as 75%. The precise amounts of the increases in the quantity of medical care per capita and in the "output per physician" can scarcely be stated herein because of a number of qualifying factors of a technical nature, but this process of deflation clearly indicates a very considerable increase in the per capita consumption of medical services by American consumers. As in other parts of this study, we are here concerned only with personal consumer expenditures.

These increases in the quantity of medical care per capita, and in the quantity of physicians' services per capita and per physician, have not occurred in isolation. They are interlocked with other social and economic changes. The increase in the gross national product, in national income, and in personal consumer expenditures were factors. The altered patterns of food distribution and consumption, improvements in transportation, and the raising of the levels of health education have helped to increase the technological efficiency of physicians. The significant increase in the use of personally owned automobiles has made it easier and more economical for the patient to consult his physician in the office and the hospital; in turn, this has reduced the physician's unproductive time spent in going to see his patients, sometimes at a considerable distance, thereby enabling the physician to see more patients and less of the countryside. The physician has also been aided by developments in the drug industry and the improvement in its products. The expansion in the range of possible treatments has placed a much greater premium on the physician's knowledge of systemic medicine, biochemistry, and a long line of related subjects, as well as upon his skills in using new tools. This, in turn, has made medical education and training longer and more expensive. The refinement and standardization of physicians' skills and the growth in the number of paramedical personnel (such as nurses, laboratory technicians, and physical therapists), the use of more and better scientific equipment in physicians' offices as well as in hospitals, and the increased concentration of people and facilities in the metropolitan centers have all contributed to the physician's increased efficiency as a producer and, hence, to a greater medical output per physician. Although such a consideration is *outside the scope of this study*, it should be noted that the services of physicians have increased the technological efficiency of the working population.

The increase in the output per physician demonstrates that a nose count of physicians or a determination of the population per physician is a highly inadequate measure of the supply of physicians' services. It is no more reasonable to use a count of physicians as a measure of supply of medical services than it is to use a count of agricultural workers as a measure of food supply. Indeed, the quality, quantity, and availability of food in the United States have increased greatly during the past quarter century, while the percentage of gainfully employed people in agriculture has been steadily declining. While in 1900 one farmer produced only enough food to supply himself and seven others, today he supplies himself and 18 others. The number of rural mail carriers has also declined, while the volume of mail delivered has increased by leaps and bounds. A dynamic economy requires that the number of persons per 100,000 population engaged in some occupations and professions should decline in order to expedite progress, whereas in other occupations and professions the number of persons per 100,000 population should increase. It is entirely possible that the tremendous increase in the technological efficiency of physicians—in the "output per physician"—and the promise of the continuance of this rapid rate of increase imply that the number of physicians per 100,000 population should decline.

ABILITY TO PAY

The foregoing discussion of changes in personal consumer expenditures for medical care and in the indexes of medical care prices raises the question of changes since 1935-1939 in the ability to pay for medical care. According to data published regularly in the *Monthly Labor Review* of the Department of Labor,[4] the average gross weekly earnings of production workers in manufacturing industries was $22.42 (computed) in 1935-1939 and $71.64 in 1954; that is, the ratio for the latter year was 3.20, a gain of 220% over the base period. A discussion of weekly wages after withholding taxes and other taxes have been deducted is beyond the scope of this study of consumers, as individuals and not as taxpayers. (Shortly before the charts were engraved and the tables set in type, we computed the average for the 12 months of 1954 as $71.64. The official average, $71.86, was not available soon enough. Consequently no corrections have been made in table 9 and chart VI—the 1954 ratio should be 3.21, not 3.20, and the hospital percentage should be 100, not 101.)

Year	Average Weekly *Earnings*	Ratio *(1935-1939 = 100)*
1935-1939	$22.42	1.00
1947-1949	53.01	2.36
1950	59.33	2.65
1951	64.71	2.89
1952	67.97	3.03
1953	71.69	3.20
1954	71.64	3.20

Consider a person who had an illness in 1937 who paid a physician $22, his wages for one week, for 11 office calls. These 11 office calls, if the unit price had changed precisely at the rate shown in the index for office visits [column (12), table 9], would have been priced 63.5% higher in 1954, or about $36. But the average gross weekly earnings in 1954 were approximately $72 instead of $36. Only 51% of the average week's wages in 1954 would have been required to purchase the amount of office visits to a physician that could have been purchased with an entire week's wages in 1935-1939. Consider also a person who spent five days in a hospital bed in 1937 at the rate of $4.50 a day, or a total of $22.50, one week's wages. The index for hospital room rates indicates that this hospital bed would have been priced at 322.1% of the base period price, or about $72.50 for the five-day stay; almost 101% of a week's pay in 1954 would have been required to purchase the amount of hospital service (five days) that could have been purchased with one week's wages in 1935-1939.

Other percentages of one week's wages in 1954 for variou items are presented in column (13) of table 9 and in chart VI. Most of these percentages are around 50 for the medical care an drugs items, with a low of 46 for a house visit and highs o 62 for an obstetric case and the 101 already noted for hospita room rates. In the lower half of the table the percentages fo the selected items show a low of 48 for rent and highs of 8 for men's street shoes and 86 for women's cotton house dresses The standard of reference here is the 60% for the group of th commodities and services included in the entire Consumer Pric Index; items for which the percentage was below 60 indicat a more favorable situation for buyers in 1954 than for the group of commodities and services included in the Consumer Price Index.

---

[4] Monthly Labor Review 78: 502, table C-2 (April) 1955.

These percentages of one week's pay, particularly those below 60, may come as a surprise, but a moment's reflection will place them in perspective. Gross weekly wages rose more rapidly than most unit prices for medical care. Broadly speaking, the earnings of the American people are related to total personal consumer expenditures. The very favorable behavior of medical care prices in relation to the stability in the percentage of total consumer expenditures for medical care items during this period points inevitably to the conclusion that the quantity of medical care purchased by the people has been increasing rapidly. This increase in the quantity of medical care that people have been able to purchase is a part of our rising standard of living. It also explains the apparent inconsistency between the very consistent relationship between personal consumer expenditures for medical care and total personal consumer expenditures on the one hand and the sharp decline in the percentage of a week's wages required in 1954 to purchase the amount (11 office calls, five days in a hospital) of medical care that would have required a whole week's wages in the base period 1935-1939. In general, a fixed unit of medical service now costs about half of a week's wages, but the people are buying many more units than in 1935.

Table 9.—*Percentage of One Week's Wages in 1947-1949 and 1950-1954 Required to Purchase the Amount of Medical Care and Other Items That Could Be Purchased with One Week's Wages in 1935-1939*

* This is the ratio appearing on page 124 of the text, obtained by dividing the average week's wages for the years subsequent to 1935-1939 by the average week's wages ($22.42) for that base period.

INCOMES OF PHYSICIANS

We have noted the stability during the quarter century of the percentage of personal consumer expenditures going for medical care items—with some increase since World War II when the number of births climbed rapidly—the slower rise in the indexes of physicians' fees than in the entire Consumer Price Index since 1935, and the considerable increase in the output per physician. The latter two factors tend to counterbalance. Income, of course, involves unit price times quantity sold. The lag in medical fees has been counterbalanced by the increase in output per physician. It is not surprising, therefore, to find that the incomes of physicians, on the average, have just about kept pace during the 25-year period with the increase in the earnings of all gainfully employed persons. This fact needs to be stressed. A chart in an advertisement by a well-known book publisher appeared in many newspapers and magazines during March, 1955. This chart seemed to imply that physicians' incomes since 1940 have increased, on the average, more rapidly than those of persons in certain selected occupations. Vague references were made to supporting data for 1940 published by the Department of Commerce, but we know of no comprehensive study of physicians' incomes for that year. Furthermore, the war in Europe was well underway in 1940, thereby eliminating that year as an acceptable base period.

Our general conclusions on physicians' incomes, presented also in chart VII, are taken directly and specifically from the *Survey of Current Business*, published monthly by the Department of Commerce. There is nothing vague about our source. The incomes of physicians in 1949 were, on the average, 108% higher than in 1929, whereas for the average earnings of wage and salary workers as well as individual business and professional workers an increase of 109% was recorded. Between 1949 and 1951 the increases were 13% and 15%.

"In the 20-year period since 1929, the average net income of all civilian physicians more than doubled, but this relative increase was practically identical with that for all earners in the general population over the same period. . . . During the same period, all earners in the general population (wage and salary workers, as well as independent business and professional workers) recorded almost the identical relative increase (109 as compared with 108 percent) as all physicians" (July, 1951, pages 9 and 10).

". . . 1949 to 1951. Physicians' incomes rose 13 percent over the period. . . . These increases in professional incomes since 1949 should be considered against the background of the general rise in money incomes and prices. From 1949 to 1951 there were increases of about 15 percent in both the over-all average earnings of employees and proprietors . . ." (July, 1952, page 5).

Since the patients and potential patients of American physicians include all the gainfully employed and their families, the proper basis of comparison, as the second quote from the *Survey of Current Business* states so clearly, is the entire body of gainfully employed people. Moreover, the reason for comparing the incomes of physicians in 1949 with those in 1929 is simply that, in the opinion of the statisticians of the Department of Commerce, there was no benchmark study of physicians' incomes in 1940 but there was one in 1929.

The surveys of physicians' income in 1949 and 1951, conducted by the Office of Business Economics of the Department of Commerce, differed in one important respect. The 1949 survey was based upon a very large sample, approximately 30,000 replies, whereas the 1951 survey was based upon fewer than 1,000 responses; also, the percentage of physicians responding was far lower in the 1951 survey than in the 1949. Although the Department of Commerce may undertake another survey of physicians' incomes in the near future, they have made no survey for the years since 1951. The long-time close relationship, 1929-1951, between the percentage increase in physicians' incomes and in the incomes of the gainfully employed suggests that this relationship would have held in 1952 and 1953. If that be true, we can conclude that physicians' incomes during the quarter century under study have kept pace with the incomes of their patients. More generally, throughout this quarter century the economic position of physicians has not changed in reference to the economic position of their patients, the American people, despite the afore-mentioned changes in personal consumer expenditures for medical care, in the indexes of medical care prices in relation to the entire Consumer Price Index, and the sharp increase in the output per physician. The physicians have been fair in the economic aspects of medical practice during this quarter century, and the people have been fair to their physicians. Thus physicians are still traveling up the center of the inflationary highway. We shall leave to others the task of drawing conclusions of this type regarding the economic position of dentists, the suppliers of drugs and sundries, hospital services, and the groups supplying the commodities and services grouped in our tables under "All Other Medical Care."

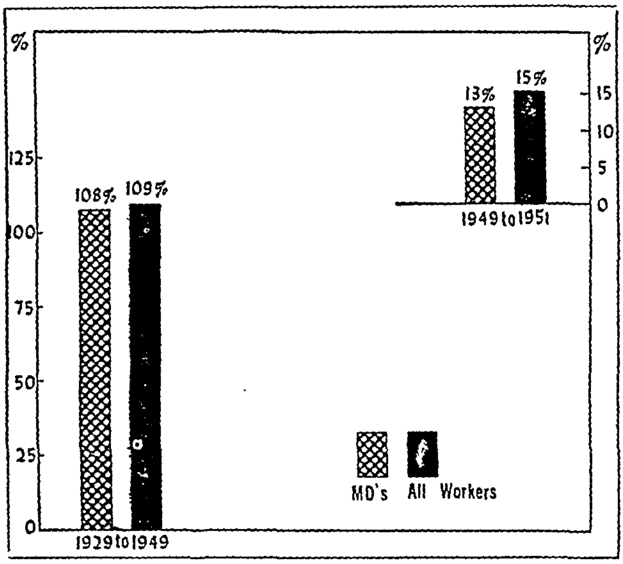

Chart VII.—Percentage increases in average incomes of physicians and of their patients. Source: U. S. Department of Commerce.

Conclusions

In attempting to describe the economic position of medical care during this quarter century, 13 tables, 8 charts, and many definitions have been employed. We have tried to answer our 10 questions set forth at the start of this discussion. The first question referred to the highlights of the expansion in the American economy during the quarter century. While the population was increasing from 122 million in 1929 to 158 million in 1953, the gross national product increased from 104 billion to 365 billion dollars (see appendix). In this national economic aggregate, government purchases of goods and services rose from 8% of the total to 23.5%. The estimated gain in physical output per capita was 57%. The dynamic character of the American economy during this quarter century was manifest not only in the changes of the types and kinds of medical care purchased by consumers but in practically all the commodities and services purchased by consumers. Perhaps the most outstanding ecc nomic change in medical care resulted from the phenomenal in crease in the number of births, an increase of 1,200,000 "bundle of joy" after World War II. This increase means that a di minishing portion of medical care expenditures is for diseas and trauma, for pregnancy is certainly not a disease. Since th text comments on these changes during the quarter centur were, at best, only a summary, no attempt will be made her to summarize them. The next 3 of the 10 questions dealt wit definitions and, accordingly, cannot be a part of the conclusion

The study has been largely limited to the private part of ou economy, what we spend as consumers and not what we spen as taxpayers. But the economic gains of this quarter centu must be tempered by a recognition of the rising national de and the additional burden placed upon the next generation b our failure to prepay the full cost of our social security pension Restricting this discussion to the private part of the econon has enabled us to avoid the puzzling questions about the mec cal care expenditures of the Department of Defense and of th Veterans Administration for the medical care of persons wi service-connected disabilities and about other similar public e *penditures, such as the desirability of adding federal farm su sidies to the expenditures for food.* It was suggested that a balan sheet of the assets and liabilities of the American people, addition to an income statement, would have enabled us properly separate and treat the private and public items, and appraise the economic gains of the quarter century.

While personal consumer expenditures were rising from billion to 230 billion dollars during the quarter century, the for medical care rose from 2.9 billion to 10.0 billion dolla Personal consumer expenditures for food, which have continu to be the largest item in the consumer budget, rose from 24.7 to 31.2% of the grand total, whereas the percentage spent f medical care ranged from 3.72 in 1929, to 3.99 in 1930, a to 4.35 in 1953. The rather steady increase in this percenta since 1945, from 4.14 to 4.35, has been due in a large mea ure to the increase in the number of births, the exceedin strong demand for the medical care of preschool children, t sharp increases in labor and other costs of operating our volu tary hospital system, and the large and persistent increase the overhead cost of operating our voluntary health insurar system; the last item is not a medical care item per se. T percentage of total personal consumer expenditures made f the services of physicians has ranged during the quarter centu narrowly from 1.1 to 1.3. The physicians' share of the medi *care dollar declined from 33 cents to 28 cents; for the servi* of dentists the decline was from 16 cents to less than 10 cen On the other hand, the hospital share of the medical care dol rose rapidly from 14 cents to 26 cents. The hospitals were mc exposed to inflation. The phenomenal health progress achiev during this quarter century probably would have been imp sible without the increasing use of hospitals.

The Consumer Price Index of the Bureau of Labor Statisti was 92% higher in 1954 than in the old base period, 1935-193 Partly because most breakdowns of this Index were not ava able for the first six years of the quarter century, the pri indexes and subindexes for 1954 were presented; thus a fif of a century of prices was reviewed. The index of the maj medical category, medical care and drugs, rose 74%; the su category for physicians' fees rose 60% (for obstetric fees, 98% and for hospital room rates, 222%. The new base period, 194 1949, is a poor base period because the postwar inflationa forces had not run their course until 1952-1954; the latter thr years would have been a better selection for a postwar ba period. It is true, however, that the subindexes for physician fees on either base period indicate that physicians' fees sinc 1947-1949 have risen more rapidly than the entire Consum Price Index, but not for the longer period.

In measuring changes in ability to pay, the comparative in creases in the average weekly earnings of production worker and in the various consumer price indexes indicated that a give quantity of medical care—11 office calls, 5 days of hospitali zation—that would have required an entire week's wages i

1935-1939 required only about one-half of a week's wages in 1954; a cross section of all commodities and services priced in the Consumer Price Index would have cost only 60% of a week's wages in 1954. The percentage of a week's wages in 1954 required for other items were: 54 for medical care and drugs; 50 for physicians' fees; 101 for hospital room rates; 48 for rent; 84 for men's street shoes; and 86 for women's cotton house dresses. The ability to pay, as measured in this fashion, has more than kept pace with the rises in the prices of these consumer items and suggests that there have been increases in the quantity of medical care purchased.

Indexes of output were computed in the traditional manner by dividing the index of personal consumer expenditures by the corresponding index of prices. Some of the resulting 1953 production indexes (1935-1939 equals 1.0) were: total medical, 2.3; physicians' services, 2.2; dentists' services, 1.6; and hospital services, 1.9. Considering the increase in the number of physicians and dentists, there were gains of about 69% in the output per physician and 33% in the output per dentist. These increases in the volume have helped to offset the failure of fees to rise as rapidly as the prices of all commodities and services since 1935-1939. Physicians have unquestionably helped to increase the technological efficiency of their patients. Despite implications to the contrary by some writers, data published by the Department of Commerce indicate that the average income (before taxes) of physicians has increased at almost exactly the same rate as the average income of all gainfully employed people since 1929. Relative to the incomes of his patients, the economic position of the physician has not changed.

Bearing in mind the tremendous changes in the patterns of consumer expenditures during this quarter century, it is clear that the medical care industry—if we may be forgiven for calling it an industry—has continued to occupy about the same economic position as it did a quarter century ago. Meanwhile the expectation of life has risen from 57 years to more than 68 years. In terms of quantity and quality of output it is quite possible that this is our most efficient industry. Social progress may be described but not precisely defined. In its essence, it is more and better years in which to enjoy and grow with more and better goods and services. In this sense, the quarter century under observation has probably been the greatest in the history of mankind. The considerable contribution of medical care to this dynamic quarter century has been achieved at reasonable cost to the patient.

Senile Osteoporosis.—[This] is a physiological condition in which bone production is less than bone resorption. It appears to be due to deficient osteoblast stimulation. Calcium metabolism and serum levels of calcium, phosphorus, and alkaline phosphatase are normal; urine calcium tends to be increased and is an index of the degree of activity of the process. One of the main etiological factors is considered to be a relative preponderance of antianabolic over anabolic hormones. The efficacy of therapy can theoretically be assessed by radiological changes, symptomatic improvement, repeated biopsies, studies with radioisotopes of calcium, or by calcium balance studies. Only the last has been proved to be a useful index at the present time. Therapy should consist of analgesia and rapid mobilization in instances in which there has been acute symptomatic fracture. Continued mobility and muscle-strengthening exercises should be obtained in all cases. Long-term maintenance is recommended on a high-protein diet with up to 1,000 mg. of calcium per day, with B vitamins and ascorbic acid if desired, but without vitamin D. Women are maintained on estrogen, with testosterone being used initially and up to the point of masculinization; men are maintained on androgen, with estrogen given initially and until femininization becomes disturbing. Continued combined androgen and estrogen therapy may be desirable in both men and women when osteoporosis is severe and general debility is present. Prolonged immobilization is to be avoided in patients with osteoporosis and in elderly patients in general. —M. Moldawer, M.D., Senile Osteoporosis, *A. M. A. Archives of Internal Medicine,* August, 1955.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACT

Privileged Communications: Names of Physician's Patients Treated in Hospital.—The Commissioner of Internal Revenue obtained an order directing the Albert Lindley Lee Memorial Hospital to turn over to the Office of Internal Revenue the names and addresses of all of Dr. Cincotta's patients who were treated in the hospital during the years 1946 to 1950. The purpose of the order was to aid the Office of Internal Revenue in an investigation of the tax returns of Dr. Cincotta. The hospital moved to dismiss the order on the ground that a New York statute extends to physicians the privilege of not having to disclose facts revealed to them in confidence by patients. The hospital maintained that it was entitled to the benefit of this statute. The order to show cause why this ruling should not be vacated was heard by the United States district court, N. D., New York.

The statute, said the court, was designed to protect disclosures made to a doctor when he is acting in a professional capacity, but the privilege extends only to personal facts not generally known to the public that might bring the patient humiliation, embarrassment, or disgrace. The information sought by the Office of Internal Revenue did not come within the scope of the privilege statute. Three facts were sought; the names of the patients, their addresses, and the fact that they were treated by Dr. Cincotta. Such facts could not be considered either as having been revealed in confidence or as being personal facts not generally known to others. The court therefore sustained the order requiring the hospital to furnish the requested information. In re *Albert Lindley Lee Memorial Hospital, 115 F. Supp. 643 (U. S., 1953).*

Workmen's Compensation Acts: Dermatitis Venenata as Accidental Injury.—An action for an award was taken under the Workmen's Compensation Act for injuries sustained from an accident occurring at work. When an award was allowed by the industrial commission, the employer appealed to the Supreme Court of Mississippi. The claimant worked in the defendant's bakery and, for the purpose of handling hot pans, wore a baker's mitten, called Jomac. Subsequently a rash developed on his hands and arms, which his doctor diagnosed as dermatitis venenata. After a temporary layoff from work the trouble disappeared, but upon his return to work the disease immediately reappeared. Allergy tests with the mitten were then performed, and the results showed that the claimant had contracted the disease because of an allergy to either the material or some chemical in the mitten. In bringing a suit for workmen's compensation the claimant contended that he had suffered an accidental injury, not an occupational disease.

The Supreme Court said that an accident, as generally understood, is an unexpected event. To this extent the contracting of dermatitis venenata was an accident, since it was the unexpected result of wearing the baker's mitten. Under the workmen's compensation law a compensable accident need not happen suddenly, nor as a result of the application of an external force. All that need be shown is that a causal factor, which existed or took place within a reasonably determinable period of time, brought about the accidental injury and that the causal factor arose out of the scope of the employment. The Supreme Court found that this requirement was met by the claimant, since the facts indicated that the injury was directly caused by the contact with the mitten, which contact took place within the scope of his employment and during a reasonably determinable period of time. Continuing, the Supreme Court said that an occupational disease is one that is commonly known to be a concomitant of a particular occupation. The claimant's dermatitis venenata was not a disease concomitant with the bakery occupation because the average baker would not contract the disease by wearing a mitten like the one worn by the claimant. The claimant contracted the disease only because of a peculiar susceptibility to it. Accordingly, the award in favor of the claimant was affirmed. *Hardin's Bakeries v. Ranager, 64 So. 2d 705 (Miss., 1953).*

MEDICAL NEWS

CALIFORNIA

Postgraduate Conferences.—Stanford University School of Medicine announces postgraduate conferences, "Important Recent Advances in Treatment in General Practice" (Sept. 12-14, $75) and "Recent Advances in General Surgery and Surgical Anatomy" (Sept. 12-16, $125). Applications for registration should be made to the Office of the Dean, Stanford University School of Medicine, 2398 Sacramento St., San Francisco 15.

Symposiums on the Campus.—Three medical symposiums, sponsored by the Orange County and Riverside County Medical Associations and the San Bernardino County Medical Society, the School of Medicine at the University of California at Los Angeles, and the University of California Extension, will be presented this fall on the Riverside campus of the university: "What's New in Medicine," Sept. 21, 1-9:15 p. m.; "Obstetrics," Sept. 28, 2:30-9:30 p. m.; and "Fevers of Unexplained Origin," Oct. 5, 9 a. m.-5 p. m. Fees are $17.50 for one symposium, or $50 for all three. Application or requests for information should be made to: Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, University of California Medical Center, Los Angeles 24, or telephone GRanite 8-9711 or BRadshaw 2-8911, extension 202.

CONNECTICUT

Personal.—Dr. Edward J. Lynch retired recently as superintendent and medical director of Laurel Heights State Tuberculosis Sanatorium after 38 years of service.——Dr. William H. Upson, Suffield, was recently elected president of the Connecticut Public Health Association. Dr. Edward M. Cohart, New Haven, was named president-elect.

Floods Cancel Industrial Health Symposium.—The Industrial Health Symposium scheduled for Sept. 22 at the United States Rubber Company, Footwear Division, in Naugatuck (The Journal, Aug. 13, 1955, page 1375), has been canceled because of flood conditions. The symposium had been planned by the committee on industrial health, Connecticut State Medical Society.

Seminar in Neurology.—Dr. Joseph A. Beauchemin, Middletown, director, Connecticut Postgraduate Seminar in Psychiatry and Neurology, announces that sessions in clinical neurology, neuroroentgenology, electroencephalography, neuroanatomy, neurophysiology, and neuropathology will be held on Mondays and Wednesdays, Sept. 25-Dec. 5, from 3 to 9 p. m. at Yale University School of Medicine, New Haven. There are no fees.

GEORGIA

Society News.—The Georgia Society of Ophthalmology and Otolaryngology recently elected the following officers: Dr. Alton V. Hallum, Atlanta, president; Dr. William L. Barton, Macon, vice-president; and Dr. Walter P. Rhyne, Albany, secretary-treasurer.——At the annual meeting of the Georgia Society of Anesthesiologists in Augusta, Drs. Stuart C. Cullen, Iowa City, and David A. Davis, Chapel Hill, N. C., were guest speakers. The following officers were elected for the coming year: chairman, Dr. William H. Galvin, Emory University; secretary-treasurer, Dr. Lester Rumble Jr., Atlanta; delegate, Dr. Edwin L. Rushia, Augusta; and alternate, Dr. Hayward S. Phillips, Augusta.——The Georgia Diabetes Association plans to hold at least one large clinical meeting each year at the time of the convention of the state medical association. A semiannual meeting is planned for this September in Atlanta. Physicians who join before the September meeting will be considered charter members. Application for membership should be submitted to any of the following officers: Dr. Christopher J. McLoughlin, president, 1010 Medical Arts Bldg., Atlanta; Dr. George R. Dillinger, vice-president, 314 S. Broad St., Thomasville; or Dr. Alex T. Murphey, secretary-treasurer, 1719 Walton Way, Augusta.

IDAHO

General Practice Meeting in Boise.—The Idaho Academy of General Practice will hold its annual meeting at the Boise Hotel in Boise, Sept. 23-24, in conjunction with the cancer society meeting. Guest speakers will include the following physicians from the University of Utah School of Medicine, Salt Lake City: Emil G. Holstrom, "Differential Diagnosis of Lesions of Cervix and Vulva"; L. Paul Rasmussen, "The Premature, Care of the Newborn and Feeding Problems in Infancy"; and Russell M. Nelson, "Surgical Approach to the Problem of Advanced Malignancy." Dr. Emory L. Soule of St. Anthony is program chairman. On Saturday there will be a football game between the University of Idaho and University of Utah at Boise.

ILLINOIS

Clinics for Crippled Children.—The University of Illinois division of services for crippled children has scheduled the following clinics to which any private physician may refer or bring children for examination or consultative services:

Sept. 13, Peoria, Children's Hospital; East St. Louis, St. Mary's Hospital.
Sept. 14, Joliet, Will County Tuberculosis Sanatorium (Sunny Hill Sanatorium).
Sept. 15, Anna, City Hospital; Rosiclare, Y.M.C.A. Building.
Sept. 16, Evanston, St. Francis Hospital.
Sept. 20, Centralia, Recreation Center.
Sept. 21, Evergreen Park, Little Company of Mary Hospital; Jacksonville, Our Saviour's Hospital.
Sept. 22, Rockford, St. Anthonys Hospital; Bloomington, St. Joseph's Hospital; Chester, Lutheran School.
Sept. 23, Chicago Heights (rheumatic fever), St. James Hospital.
Sept. 27, Peoria, Children's Hospital; Effingham (rheumatic fever), St. Anthony's Emergency Hospital.
Sept. 28, Springfield (cerebral palsy), Memorial Hospital; Aurora, Copley Memorial Hospital.

Chicago

Volunteer Medical Company.—A meeting of the Volunteer Medical Company 9-20, U. S. Naval Reserve, will be held at the U. S. Veterans Research Hospital, Room A-302, 333 E. Huron St. (MOhawk 4-6600), 8:15 p. m., Sept. 13. "Kidney Function in Health and Disease" (movie) will be presented by Drs. Arthur C. Corcoran, Cleveland, Don Carlos Hines, Indianapolis, and Irvine H. Page, Cleveland.

Fund to Help Disabled Practitioners.—The executive director of the Dr. Adolph Gehrmann fund announces that funds are available for sick and disabled practicing physicians who are in need of financial assistance in their attempt to regain health and for the widow of a physician for a period of not greater than one year after the death of her husband. The fund cannot be used as an old age pension for physicians but must help, adhering to the statement in the will, "in his or their attempt to regain health." Applications for assistance should be made to Mr. James Brown IV, Executive Director of the Chicago Community Trust, 10 S. LaSalle St., Chicago 3.

KENTUCKY

University News.—Dr. William C. Adams, Ridgewood, N. J., has been appointed instructor in child health at the University of Louisville School of Medicine.——Ten class reunions (fifth year classes, 1905-1950) of the University of Louisville School of Medicine will be held in Louisville during the annual meeting of the Kentucky State Medical Association Sept. 27-29. The reunion dinners will follow a cocktail party given by the medical school faculty in the Brown Hotel at 5 p. m. Thursday. It is

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

planned to have class reunions of Louisville medical school graduates in conjunction with the Kentucky State Medical Association annual meeting each year in the future. In 1956, the 10 classes will start with the year 1906 and continue with each consecutive fifth year through 1951.

State Medical Meeting in Louisville.—The Kentucky State Medical Association will hold its annual meeting (the Jerman Baker Memorial Meeting) Sept. 27-29 in the Columbia Auditorium, Louisville, where welcoming remarks will be made by Dr. Gradie R. Rowntree, Louisville, president, Jefferson County Medical Society. Dr. Clyde C. Sparks, Ashland, president of the state society, will deliver the presidential address at 10 a. m. Dr. Elmer Hess, Erie, Pa., President of the American Medical Association, will address the president's luncheon Wednesday, 11:45 a. m., on "What the Physician Owes His Patient." Presentations by out-of-state speakers during the scientific sessions will include:

Variations in the Disease, Pulmonary Tuberculosis, Edgar M. Medlar, Ithaca, N. Y.
Urologic Pathology of Interest to the General Practitioner, Frank M. Woods, Miami, Fla.
Role of the Medical Department in Today's Navy, Adm. Ocie B. Morrison Jr., Portsmouth, Va.
Convulsive Seizures in Infancy and Childhood, James G. Hughes, Memphis, Tenn.
Adrenal Cortical Hormones as Therapeutic Agents, Albert Segaloff, New Orleans.
The Changing World for Medicine, Austin Smith, Chicago, Editor of THE JOURNAL.
Effect of Anesthetic Agents on the Heart, David A. Davis, Chapel Hill, N. C.
Gastric Ulcer—Criteria for Determining Method of Treatment, Harold J. Kullman, Dearborn, Mich.
A Case for Social Medicine, Peter L. Scardino, Savannah, Ga.

Thursday afternoon will be devoted to the programs of nine specialty groups. The morning and afternoon sessions on Tuesday and Wednesday and the morning session on Thursday will begin with color television, eight hours in all being devoted to this medium.

MONTANA

Society News.—The Montana Society of Pathologists recently elected Dr. Edwin C. Segard, Billings, president; and Dr. John A. Newman, Butte, secretary.

Personal.—Dr. Sidney A. Cooney, Helena, a past-president of the Montana Medical Association, was honored by the Lewis & Clark Medical Society at a testimonial banquet for his approaching 50th anniversary in the practice of medicine. Dr. Edward S. Murphy, Missoula, served as master of ceremonies, and testimonials were presented by Dr. James M. Flinn, Helena, Dr. Edmund A. Welden, Lewistown, Dr. R. O. Lewis, Helena, president of the society, and Mr. L. R. Hegland, executive secretary of the Montana Medical Association. Dr. Cooney, who has long been active and interested in public health and medical and athletic affairs, has served as a member of the board of medical examiners for 35 years and as its secretary for 24 years.

State Medical Meeting in Bozeman.—The 77th annual meeting of the Montana Medical Association will convene in the Student Union Building on the campus of Montana State College, Bozeman, Sept. 15-18. Scientific sessions will open at 9 a. m. with an address of welcome by Dr. Francis I. Sabo, Bozeman, president, Gallatin County Medical Society, to which response will be made by Dr. John J. Malee, Anaconda, president, Montana Medical Association. Guest speakers and their first presentations will include:

Michael L. Mason, Chicago, Management of Burns.
Daniel C. Darrow, Kansas City, Kan., Pathogenesis of Metabolic Alkalosis.
Benjamin Felson, Cincinnati, Recent Advances in Roentgen Contrast Visualization.
Leonard A. Lang, Minneapolis, Deflexion Attitudes.
Robert J. Bolt, Ann Arbor, Mich., Newer Measures for Evaluating Gastric Function and Early Detection of Gastric Carcinoma.
Jerome A. Hilger, St. Paul, Bronchologic Methods in Pulmonary Diagnosis.
Sture A. M. Johnson, Madison, Wis., Diagnosis and Treatment of Some Common Skin Disorders.
Merrill J. Reeh, Portland, Ore., The Glaucoma Problem.

A clinicopathological conference will be presented Thursday at 1:45 p. m., with Dr. Paul J. Gans, Lewistown, as moderator. Dr. George T. R. Fahlund, Great Falls, will serve as moderator for a symposium on trauma Friday, 1:15 p. m. Dr. David Gregory, Glasgow, will moderate a clinicopathological conference Saturday at 1:15 p. m. The annual reception will precede the banquet Thursday, 8. p. m., at which Dr. Raymond E. Benson, Billings, will serve as toastmaster and the Hon. John C. Vivian, Denver, will speak on "The State of the Nation." The Gallatin County Medical Society will be host to all members and guests of the association at a dance and buffet supper at Gallatin Gateway Inn, Friday, 8:30 p. m. The Montana Physicians' Service will be host at a friendship hour and cocktail party Saturday, 6-8 p. m., at the Baxter Hotel. The woman's auxiliary will meet simultaneously with the parent organization. At the auxiliary luncheon meeting Thursday, 12:30 p. m., Dr. George W. Setzer, Malta, president-elect of the Montana Medical Association, will deliver greetings.

NEW YORK

Nutrition Workshop.—A "Nutrition Workshop" is being planned by the Medical Society of the County of Monroe, with the cosponsorship of the Rochester-Monroe County chapter of the American Red Cross, Rochester-Monroe County Nutrition Committee, and the Rochester Dietetic Association, for Sept. 22 at the Rochester Gas and Electric Company's auditorium. There will be afternoon discussion groups on diabetes, arteriosclerosis, heart disease, and obesity. In the evening, Dr. James H. Hundley, chief of the laboratory of biochemistry and nutrition in the National Institute of Arthritis and Metabolic Disease, Bethesda, Md., will talk on nutrition.

New York City

Workshop in Medical Writing.—The Washington Square Writing Center at New York University's division of general education will present a "Workshop in Writing for Medical and Scientific Journals" and "Techniques of Practical Writing" as part of its fall program for adult students, who may enroll for courses from Sept. 12 to 30. Information can be obtained from the Division of General Education, New York University, 1 Washington Square North, New York 3.

Research Expedition to Amazon.—Dr. Hans H. Neumann, research assistant in dentistry, and Nicholas A. DiSalvo, Ph.D., assistant professor of physiology, Columbia University College of Physicians and Surgeons, have flown to the upper Amazon valley, where they will lead a six week expedition to study the diet of isolated Indian tribes in connection with dental caries and will collect data from a biophysical rather than from a biochemical angle. Dr. Neumann initiated his study in 1939. The present expedition will be a continuation of observations he has made around the globe in such places as Polynesia and India. South American scientists are expected to join the expedition.

OHIO

Grants in Hypertension and Cancer Research.—Research grants of more than $90,000, recently awarded to Dr. Harry Goldblatt, director of laboratories, and Erwin Haas, Ph.D., biochemist, for continuation of research on high blood pressure and cancer at Mount Sinai Hospital, Cleveland, include $20,000 from the Louis D. Beaumont Trust and $73,000 from the U. S. Public Health Service.

OREGON

Personal.—Dr. Arthur J. O'Toole, Portland, has been named coroner for Multnomah County to succeed the late Dr. F. Floyd South. Dr. O'Toole serves on the staffs at Portland Sanitarium and Hospital and Providence and St. Vincent's hospitals, Portland, and will continue in private practice.——Dr. Adolph Weinzirl, head, department of public health and preventive medicine, University of Oregon Medical School, Portland, has been appointed by Governor Paul Patterson to serve on a nine-man interim committee to study sex crime prevention. The committee also will consider the cause and prevention of sex deviation and abnormalities and submit their recommendations to the governor and the legislature before the next session convenes.

State Medical Meeting in Portland.—The 81st annual session of the Oregon State Medical Society and the 8th annual meeting of the Oregon Academy of General Practice will be held in conjunction with the 22nd Sommer Memorial Lectures, Sept. 27-30 at the Masonic Temple, Portland. The Sommer memorial guest lecturers will present the following lectures:

- Cyrus C. Sturgis, professor of medicine, University of Michigan Medical School, Ann Arbor, (1) Etiology and Treatment of Hematologic Disorders. (2) Diagnosis and Management of Toxic Thyroid States and Cancer of the Gland. (3) Nature and Treatment of Various Forms of Leukemia and Allied Disorders.
- George T. Pack, clinical professor of surgery, New York Medical College, New York, (1) Tumors of the Soft Somatic Tissues. (2) Moles and Melanoma. (3) Surgical Treatment of Primary and Secondary Liver Tumors.
- Edgar A. Pask, professor of anesthetics, University of Durham Medical School, Newcastle Upon Tyne, England, (1) What is the Anesthesiologist Seeking To Do? (2) Jimmy Brown's Ordinary Operation: Part of the Surgical Adventures of One Patient. (3) Ordinary Troubles with Anaesthetics.

The guest lecturer of the Oregon Academy of General Practice, Dr. Alec M. Agnew, professor of obstetrics and gynecology, University of British Columbia Faculty of Medicine, Vancouver, B. C., Canada, will discuss "Problems in Stage O Carcinoma of the Cervix," "Obstetrical Emergencies," and "Indications for Hysterectomy."

PENNSYLVANIA

Rush Award Winners.—Winners of the Benjamin Rush award, presented each year by the Medical Society of the State of Pennsylvania to laymen contributing outstanding service to their communities in the field of public health, have been announced as Stanley Franklin Fink, Ed.D., Reading, and the Rotary Club of Allentown. Dr. Fink, principal of Southwest Jr. High School, Reading, was selected chiefly for his work in collecting funds for the treatment of children with cerebral palsy. He has also been director of Reading's first recreational center; chairman of the Free Eyeglass Fund for School Children; board member of the Pennsylvania Society for Crippled Children and Adults, Reading chapter president and a national officer of the American Business Clubs, and he now becomes the first two-time winner of the award in Berks County. The Rotary Club of Allentown has taken leadership in a variety of programs dealing with health, including a cerebral palsy nursing school, a preschool age hearing clinic, a health lodge at the Boy Scouts' Camp Trexler, aid to crippled children at camp, equipment for retarded children, and nursing scholarships. The two state winners will be presented with bronze medallions at the state dinner during the 105th annual meeting of the society in Pittsburgh on Sept. 20.

TEXAS

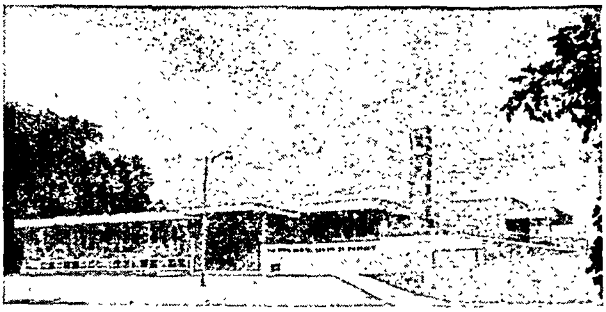
Industrial Health Conference.—The eighth annual Industrial Health Conference will be held Sept. 22-24 at the Shamrock-Hilton Hotel, Houston. The conference will open with official greetings by Roy A. Hofheinz, mayor, city of Houston. A symposium on agricultural health problems is scheduled for Thursday afternoon. Dr. Lemuel C. McGee, medical director, Hercules Powder Company, Wilmington, Del., will discuss "Problems of Agricultural Chemicals"; W. W. Armstead, dean, school of veterinary medicine, Texas A & M College, College Station, will consider "Diseases Transmittible to Man from Animals"; and Dr. H. Herman Young, Mayo Clinic, Rochester, Minn., will have as his topic "Accidents in Agricultural Operations." The Friday morning session will open with a symposium on rehabilitation, in which "Development of Rehabilitation Facilities" will be discussed by Dr. Robert L. Bennett, director, Georgia Warm Springs Foundation Clinic, and "Financial Aspects of Rehabilitation" by Mr. Standwood L. Hanson, vice-president, claims department, Liberty Mutual Insurance Company, Boston. The luncheon address will be delivered by Cyril L. Comar, PhD., of the Oak Ridge (Tenn.) Institute of Nuclear Studies. Dr. William P. Shepard, New York, will preside at the panel discussion Friday afternoon, presented by the A. M. A. Council on Industrial Health, of which he is Chairman. "Practical Applications of Current Research" will be considered at 2 p. m. and "Problems of Health in an Industrial Society" at 3 p. m. On Saturday morning Dr. Henry A. Holle, Austin, commissioner, state department of health, will speak on the industrial nurse's contribution to public health and Dr. Bennett on rehabilitation after injury. The afternoon will be devoted to a tour of the Light House for the Blind.

WASHINGTON

Obstetricians Meeting in Seattle.—The fall meeting of the Washington State Obstetrical Association will be held at the Washington Athletic Club, Seattle, Sept. 24. Guest speakers will be (1) Dr. Leroy A. Calkins, professor of obstetrics and gynecology, University of Kansas School of Medicine, Lawrence-Kansas City, whose topics will be "Bregma, Brow and Face, and Transverse Presentation" and "Fetal Mortality," and (2) Dr. Willis E. Brown, professor of obstetrics and gynecology, University of Arkansas School of Medicine, Little Rock, who will discuss "Management of Prolonged Labor" and "Clinical Experience with Eclampsia." Dr. R. Philip Smith of Seattle will be moderator of the noon round-table luncheon. At the banquet, Dr. Richard J. Blandau of the University of Washington School of Medicine will show a film of his work on ovulation.

WISCONSIN

New Headquarters of State Medical Society.—The offices of the State Medical Society of Wisconsin in Madison were transferred in June from 704 E. Gorham St. on Lake Mendota to 330 E. Lakeside St. on Lake Monona. The ground floor, which opens directly onto the lake side of the property, houses the Blue Shield administrative offices, service room, supply room, kitchen, and dining room. The top floor provides space for the reception room, two consultation rooms, a secretary's office, library conference room, offices for administrative purposes, and a council room. The new headquarters afford a large parking area for employees and visiting physicians. It is anticipated that the building will be completed and ready for use about mid-October.



Headquarters of State Medical Society of Wisconsin

Home Therapy Service for Arthritic Patients.—The Wisconsin chapter of the Arthritis and Rheumatism Foundation has announced the establishment of a nursing and physical therapy service for home-bound patients, in cooperation with the Visiting Nurse Association. Services of the unit, which will be operated by a physical therapist from the Visiting Nurse Association, will be available to patients who are referred by their physician. Dr. Edwin C. Welsh, Milwaukee, is in charge of the program. Information may be obtained from the Wisconsin Chapter of the Arthritis and Rheumatism Foundation, 208 E. Wisconsin Ave. (BR 1-4131).

Personal.—Dr. Phillip R. McCanna, Marinette, has accepted an appointment in ophthalmology at the University of Illinois College of Medicine, Chicago.——Dr. James J. Foster, formerly of Madison, is the new medical director of the Milwaukee Cancer Diagnostic Clinic, succeeding Dr. Richard J. Krill, who left the clinic to complete residency training in surgery at Presbyterian Hospital, New York. Dr. Krill plans to return to Milwaukee after completing his training.——Dr. Errol V. Brumbaugh, West Allis health commissioner, and Dr. Fred B. Welch, Janesville health commissioner, have been awarded honorary life memberships in the Wisconsin Association for Public Health.

GENERAL

Meeting of Southern Trudeau Society.—The Southern Trudeau Society will meet at the Brown Hotel, Louisville, Ky., Sept. 21-23. Subjects for discussion include tuberculosis and the general practitioner; problems in chemotherapy; and nontuberculous disease. A Pembine-type consecutive case conference will be presented Thursday evening by a group of Kentucky physicians, with Dr. John S. Harter, Louisville, as chairman.

Association of Nursing Homes.—The annual convention of the American Association of Nursing Homes will meet in the Auditorium, Kansas City, Mo., Sept. 19-21. Physicians who will address the association include Dr. William F. King, Indianapolis; Dr. John M. Whitney, Battle Creek, Mich., luncheon speaker, Tuesday; Dr. John W. Cronin, Washington, D. C., who will address the annual banquet Tuesday, 7 p. m.; and Dr. Edward H. Hashinger, Kansas City, Mo., who will address the luncheon meeting Wednesday.

Course on Venereal Disease.—The 24th Venereal Disease Postgraduate Course for physicians, sponsored by the University of Chicago and the Public Health Service, will be given at the university Sept. 26-30. The course, accredited by the American Academy of General Practice, is designed to acquaint the practitioner with the latest developments in diagnosis, treatment, and management of venereal disease. No tuition will be charged. Applications for admission should be sent to the Section on Dermatology, Department of Medicine, University of Chicago, Chicago 37.

Fellowships for Research in Arthritis.—The Arthritis and Rheumatism Foundation is offering the following research fellowships in the basic sciences related to arthritis: 1. Predoctoral fellowships ($1,500-$3,000 per annum, depending on the family responsibilities of the fellow), tenable for one year with prospect of renewal. 2. Postdoctoral fellowships ($4,000-$6,000 per annum, depending on family responsibilities), tenable for one year with prospect of renewal. 3. Senior fellowships for more experienced investigators ($6,000-$7,500 per annum), tenable for five years. The deadline for applications is Oct. 15. Applications will be reviewed and awards made in January, 1956.

Research Fellowships and Grants.—Applications for awards available July 1, 1956, will be received by the Life Insurance Medical Research Fund as follows: (1) postdoctoral research fellowships, until Oct. 15, 1955, with preference to those who wish to work on cardiovascular function and disease or related fundamental problems (minimum stipend $3,600, with allowances for dependents and necessary travel) and (2) grants to institutions in aid of research on cardiovascular problems, until Nov. 1, 1955. Support is available for physiological, biochemical, and other basic work broadly related to cardiovascular problems as well as for clinical research in this field. Predoctoral fellowships will not be offered by the fund this year. Information may be obtained from the Scientific Director, Life Insurance Medical Research Fund, 345 E. 46th St., New York 17.

Hospital Association Convention.—The 57th annual American Hospital Association convention and the 8th annual Conference of Hospital Auxiliaries will be held in Atlantic City, N. J., Sept. 19-22. Over 100 round-table discussions will supplement the four key general sessions. A postconvention cruise to Bermuda has been planned aboard the S. S. Queen of Bermuda, Sept. 24-30. The cost ($174.30—$245.80) includes room and meals, both aboard ship and in a resort hotel on the island, as well as a special tour of the island. The ship leaves New York City at 3 p. m. Saturday and returns on Friday. Persons who wish to remain on the island another two days may return by air (cost for this trip, $194.05—$229.80). Trip reservations should be sent to Aladdin Travel Service, 220 South State St., Suite 506, Chicago 4.

Frank L. Chance Research Fellowships.—The City of Hope National Medical Center, Duarte, Calif., announces that two Frank L. Chance Research Fellowships (one in hematology and one in medical oncology) will be available this year. Inquiries should be directed to Dr. Howard R. Bierman, scientific director, before Oct. 1. The fellowships were established by the late Mrs. Frank L. Chance in honor of her husband of baseball's famed double-play team, Tinker-to-Evers-to-Chance. Five fellowships are available each year for periods of one to three years. Fellows selected hold an appointment in the Medical Research Institute of the City of Hope Medical Center, with a dual title in one of the hospitals of the center if clinical research is to be done. The annual stipend varies from $3,600 to $5,000. The fellowships were designed to afford special training in the fields in which the City of Hope Medical Center is engaged: (1) tumors and allied diseases, (2) hematology, (3) cardiac disease amenable to surgery, and (4) cardiorespiratory diseases.

Tri-State Obstetric Seminar.—A seminar on obstetrics will be held at the Daytona Plaza Hotel, Daytona Beach, Fla., Sept. 12-14, under the sponsorship of the South Carolina Medical Association, the Medical Association of Georgia, the Florida Medical Association, and the bureaus of maternal and child health of the state health departments of South Carolina, Georgia, and Florida. The Monday program, which will be devoted to pediatrics, will open with a paper on immunization by Dr. Robert B. Lawson, Miami, Fla., after which "Health Supervision of Young Children" will be considered by Dr. Samuel M. Wishik, Pittsburgh. "Major Medical Problems Complicating Pregnancy" will be discussed on Tuesday by Dr. Norman Thornton and "Obstetrical Care in Rural Communities" by Dr. Robert A. Ross, Chapel Hill, N. C. The Wednesday session will include "Toxemia—Recent Advances in Treatment" by Dr. William J. Dieckmann, Chicago; "Afibrogenopenia in Pregnancy" by Dr. Carl P. Huber, Indianapolis; and "Anomalous Products of Pregnancy" by Dr. John L. Parks, Washington, D. C. All physicians are welcome. There is no registration fee.

Meeting on Medicinal Chemistry.—The 128th national meeting of the American Chemical Society will be held at the University of Minnesota, Minneapolis, Sept. 11-16. The fourth annual Symposium on Cancer will be presented Friday. Louis F. Fieser, Ph.D., Belmont, Mass., will preside at the morning session on "Metabolic Conversions of Steroids," which will include the following presentations:

Conversions of Steroids by Microorganisms, Albert Wettstein, Basle, Switzerland.
Biogenesis of Steroid Hormones, Ralph I. Dorfman, Ph.D., Shrewsbury, Mass.
Studies of the Steroid Hormones in Man, Thomas F. Gallagher, Ph.D., New York.

Dr. Charles B. Huggins, Chicago, will preside at the afternoon session on steroids and cancer, when the following presentations will be made:

Inherited Hormonal Mechanisms and Mammary Cancer in Mice, John J. Bittner, Ph.D., Minneapolis.
Endocrine Carcinogenesis, Eric S. Horning, London, England.
Endocrine Control of Neoplasms in Man, Olof H. Pearson, New York.

The Friday sessions will conclude with the chairman's summary by Dr. Huggins and the symposium summary by Dr. Cornelius P. Rhoads, New York.

Roentgen Ray Society.—The 56th annual meeting of the American Roentgen Ray Society will be held at the Palmer House, Chicago, Sept. 20-23. The meeting will be called to order at 8:30 a. m. by Dr. Joshua C. Dickinson, Tampa, Fla., president, after which Lawrence A. Kimpton, Ph.D., chancellor of the University of Chicago, will deliver the address of welcome. Dr. Paul C. Hodges, Chicago, who will be installed as president, will deliver his inaugural address, "Radiology in the Seventh Decade." The Caldwell Lecture, "A New Concept of the Etiology of Duodenal and Gastric Ulcer," will be given at 8:30 p. m. Tuesday by Dr. Lester R. Dragstedt, chairman, department of surgery, University of Chicago, to whom the medal of the society will be presented by Dr. Egbert H. Fell, Chicago. A symposium on gastrointestinal diseases has been scheduled for Wednesday morning and a symposium on supervoltage and megavoltage radiation therapy with various sources for Thursday morning. Some 36 persons will participate in the program by invitation. These include Dr. Carl Wegelius, Stockholm, Sweden; Dr. Charles C. Burkell and Thomas A. Watson, M.B., Saskatoon, Saskatchewan, Canada; and Dr. Ivan H. Smith, London, Ontario, Canada. The annual banquet Thursday evening will be preceded by cocktails at 6:30 p. m.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Conference on Psychiatry.—The American Psychiatric Association will hold its Midwest Regional Research Conference Sept. 16-17 at Galesburg, Ill., with the cosponsorship of the University of Illinois College of Medicine, Chicago, and the Galesburg (Ill.) State Research Hospital. The conference, the theme of which is "A Comprehensive Evaluation of the Newer Psychopharmacologic Agents and Their Role in Current Psychiatric Practice," will be opened Friday at 9 a. m. by Dr. Otto L. Bettag, Chicago, director, Department of Public Welfare. The morning session will be devoted to "The Neurophysiology and Neuropharmacology of the New Drugs" (chairman, Dr. Percival Bailey, Chicago) and the afternoon session to "The Relative Values of Drugs in the Various Psychiatric Syndromes" (chairman, Dr. Jacques Gottlieb, Detroit). A cocktail hour (courtesy of Smith, Kline & French Laboratories) will precede dinner, 7 p. m., at the Hotel Custer. Dr. Lester H. Rudy, Galesburg, will serve as the chairman for the Saturday morning session on "The Significance and Management of the Complications Resulting from New Drugs," which will be addressed by Drs. Anthony A. Sainz, Marcy, N. Y., Douglas Goldman, Cincinnati, Frank J. Ayd Jr., Baltimore, and Vernon J. Kinross-Wright, Houston, Texas. A tour of the Thudichum Psychiatric Research Laboratory, Galesburg State Research Hospital, will precede luncheon at the hospital. Saturday afternoon will be devoted to a symposium, "The Role of Drug Therapies in Current and Future Psychiatric Practice," in which the moderator will be Dr. Francis J. Gerty, Chicago, and the participants Drs. C. Knight Aldrich and Jules H. Masserman, Chicago, Dr. Paul H. Hoch, New York, and Dr. Lauren H. Smith, Philadelphia.

LATIN AMERICA

Congress on Bronchoesophagology.—The fourth International Congress and fifth Argentine Congress of Bronchoesophagology will convene in Buenos Aires, Argentina, Oct. 28-29 to discuss (1) laryngotracheobronchopathies in children; (2) non-neoplastic stenosis of the esophagus; and (3) free subjects. Physicians wishing to participate must send their articles before Sept. 15 to the Secretary of the Congress, Dr. Juan C. Aráuz, Canjallo 4015, Buenos Aires, Argentina, S. A.

FOREIGN

Symposium on Disease Transmission.—The Institute of Biology will present a symposium, "Biological Aspects of the Transmission of Disease," at the London School of Hygiene, Keppel Street, London, W. C. 1, England, Sept. 29-Oct. 1.

Congress on Prophylactic Medicine.—The fourth International Congress of Prophylactic Medicine will be held in Bad Reichenhall, Germany, Sept. 30-Oct. 4. The subjects to be discussed include Climatology and Balneology; Environmental Influences; Care of the Healthy and of the Sick with Respect to Industrial Injuries; and Mental Hygiene.

Meeting on Obstetrics and Gynecology.—The 16th Congress of the Federation of French-Speaking Gynecologic and Obstetric Societies will convene at the Free University of Brussels, 50 av. Franklin Roosevelt, Brussels, Belgium, Sept. 22-26. Reports will be given on "Treatment of Congenital and Acquired Deformities of the Vulva and Vagina (Prolapse Excluded)," "Postpartum Endocrine Syndromes," and "Therapy of Pregnancy Toxicoses."

Course on Tomography.—The third International Course on Tomography will be held Oct. 3-12 at the Radiology Institute of the University of Genoa in Italy. Lectures on theory, geometric studies, technique and instruments, and applications of tomography in examination of several organs in the normal and the pathological subject will be presented, and special attention will be drawn to recent progress in tomographic method. Information may be obtained from the General Secretary, Dr. Luigi Oliva, Instituto di Radiologia, Ospedale S. Martino, Genoa, Italy.

International Meeting on Forensic Medicine.—The first International Congress of Medical Professional Jurisdiction, Medical Ethics, and Comparative Medical Law will be held in Paris from Sept. 30 to Oct. 3. Medical ethics will be considered under the following topics: (1) Moral Reasons for Medical Secrecy, (2) Consent of the Patient to Medical Action, (3) Independence of the Physician, and (4) Moral Conditions for the Application of New Methods of Diagnosis and Treatment. The meeting on comparative medical law will include a report based on replies to questionnaires sent to competent individuals and institutions in various countries, concerning (1) medical secrecy as affected by public and private methods of health insurance and (2) the conditions governing the practice of medicine. Fees for enrollment at the congress are 5,000 francs (about $14.50) for active members and 2,500 francs (about $7.50) for ladies. A social and recreational program is being arranged. Correspondence should be addressed to the Conseil National de l'Ordre des Medecins, 60, boulevard Latour-Maubourg, Paris (7e), France.

CORRECTION

Dosage of Corticotropin.—In the clinical note, "Corticotropin in Severe Anginose Infectious Mononucleosis," in The Journal, July 23, 1955, page 1021, fifth line, third paragraph, right-hand column, the doses given should read "15, 10, 7.5, 5, and 2.5 U. S. P. units for a total of 40 units."

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Oct. 12-14. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago, Director.

Academy of Psychosomatic Medicine, Hotel Plaza, New York, Oct. 6-8. Dr. Ethan Allan Brown, 75 Bay State Road, Boston 15, Secretary.

American Academy for Cerebral Palsy, Claridge Hotel, Memphis, Tenn., Oct. 10-12. Dr. Robert A. Knight, 869 Madison Ave., Memphis 3, Tenn., Secretary.

American Academy of Neurological Surgery, The Homestead, Hot Springs, Va., Oct. 27-29. Dr. Eben Alexander Jr., Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Palmer House, Chicago, Oct. 3-6. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Executive Secretary.

American Association of Medical Clinics, Curtis Hotel, Minneapolis, Nov. 4-6. Dr. Edwin P. Jordan, Box 58, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, LaSalle Hotel, Chicago, Oct. 3-7. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Director.

American Association of Nursing Homes, Hotel Muehlebach, Kansas City, Mo., Sept. 19-21. Mr. Ira O. Wallace, P.O. Box 366, New Castle, Ky., Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 27-29. Dr. James K. Stack, 700 N. Michigan Blvd., Chicago 11, Secretary.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Oct. 31-Nov. 2. Dr. M. N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Gastroenterology, Edgewater Beach Hotel, Chicago, Oct. 24-26. Dr. Joseph Shaiken, 33 West 60th St., New York 23, Secretary.

American College of Hospital Administrators, Convention Hall, Atlantic City, N. J., Sept. 17-19. Mr. Dean Conley, 620 North Michigan Ave., Chicago 11, Executive Director.

American College of Surgeons, Conrad-Hilton Hotel, Chicago, Oct. 31-Nov. 4. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American Dental Association, San Francisco, Oct. 17-20. Dr. Harold Hillenbrand, 222 East Superior St., Chicago 11, General Secretary.

American Fracture Association, Hotel Fontainebleau, Miami Beach, Fla., Sept. 19-22. Dr. Homer D. Junkin, Paris Hospital, Paris, Ill., Secretary.

American Heart Association, Yung Hotel, New Orleans, Oct. 22-26. Mr. Irving Hexter, 44 East 23d St., New York 10, Secretary.

American Hospital Association, Traymore Hotel, Atlantic City, N. J., Sept. 19-22. Dr. Edwin L. Crosby, 18 East Division St., Chicago 10, Director.

American Medical Writers' Association, Jefferson Hotel, St. Louis, Sept. 30-Oct. 1. Dr. Harold Swanberg, P.O. Drawer 110, Quincy, Ill., Secretary.

American Roentgen Ray Society, Palmer House, Chicago, Sept. 20-23. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Anesthesiologists, Hotel Statler, Boston, Oct. 29-Nov. 3. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago 1, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 10-15. Dr. Clyde G. Culbertson, 1040-1232 West Michigan St., Indianapolis, Secretary.

American Society of Plastic and Reconstructive Surgery, Atlantic City, N. J., Sept. 25-30. Dr. Kenneth L. Pickrell, Duke Hospital Durham, N. C., Secretary.

American Society of Tropical Medicine and Hygiene, Somerset Hotel, Boston, Nov, 2-5. Dr. John E. Larsh Jr., Dept. of Parasitology, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, New Ocean House, Swampscott, Mass., Oct. 24-26. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of American Physicians and Surgeons, Chicago, Oct. 7-8. Mr. Harry E. Northam, 185 N. Wabash Ave., Chicago 1, Executive Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 19-21. Dr. Henry B. Kirkland, P. O. Box 594, Newark, N. J., Secretary.

Association of Medical Illustrators, Hotel Barbizon Plaza, New York, Oct. 1-3. Miss Rose M. Reynolds, Univ. of Nebraska College of Medicine, Omaha 5, Neb., Corresponding Secretary.

Central Association of Obstetricians and Gynecologists, Deshler-Hilton Hotel, Columbus, Ohio, Oct. 5-8. Dr. Edwin J. DeCosta, Suite 602, 116 S. Michigan Ave., Chicago 3, Secretary.

Central Neuropsychiatric Association, The Broadmoor, Colorado Springs, Colo., Oct. 20-22. Dr. Hamilton Ford, 112 North Boulevard, Galveston, Tex., Secretary.

Central Society for Clinical Research, Drake Hotel, Chicago, Nov. 4-5. Dr. Robert H. Ebert, 950 East 59th St., Chicago 37, Secretary.

Clinical Orthopaedic Society, Skirvin Hotel, Oklahoma City, Sept. 30-Oct. 1. Dr. Marcus J. Stewart, 869 Madison Ave., Memphis, Tenn., Executive Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 10-15. Dr. Arthur H. Dearing, 203 N. Wabash Ave., Chicago 1, Executive Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Congress of Neurological Surgeons, Hotel Statler, Los Angeles, Oct. 27-29. Dr. Philip D. Gordy, 1007 Delaware Ave., Wilmington, Del., Secretary.

Delaware, Medical Society of, Delaware Academy of Medicine, Wilmington, Oct. 17-18. Dr. Norman L. Cannon, 621 Delaware Ave., Wilmington, Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, D. C., Oct. 10-12. Mr. Theodore Wiprud, 1718 M St., N.W., Washington 6, D. C., Executive Director.

Gerontological Society, Sheraton-Belvedere Hotel, Baltimore, Oct. 27-29. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 27-28. Dr. Barkley Beidleman, 1750 N. Palafox St., Pensacola, Fla., Secretary.

Indiana State Medical Association, French Lick Springs Hotel, French Lick, Oct. 16-19. Mr. James A. Waggener, 23 East Ohio St., Indianapolis 4, Executive Secretary.

Industrial Health Conference, Shamrock Hotel, Houston, Texas, Sept. 22-23. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Texas, Chairman.

Kansas City Southwest Clinical Society, Municipal Auditorium, Kansas City, Mo., Oct. 3-6. Dr. W. M. Kitchen, 306 E. Twelfth St., Kansas City 6e, Mo., Secretary.

Kentucky State Medical Association, Louisville, Sept. 27-29. Mr. J. P. Sanford, 620 S. Third St., Louisville, Executive Secretary.

Michigan State Medical Society, Pantlind Hotel, Grand Rapids, Sept. 26-30. Dr. L. Fernald Foster, 606 Townsend St., Lansing 5, Secretary.

Midwest Conference on Rheumatic Diseases, Henry Ford Hospital, Detroit, Oct. 5. Dr. J. J. Lightbody, 7338 Woodward Ave., Detroit 2, Medical Director.

Midwestern Section of American Federation for Clinical Research, Thorne Hall, Northwestern University, and Drake Hotel, Chicago, Nov. 3. Dr. Robert J. Glaser, Barnes Hospital, St. Louis 10, Secretary.

Mississippi Valley Medical Society, Jefferson Hotel, St. Louis, Sept. 28-30. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Mississippi Valley Trudeau Society, Hotel Savery, Des Moines, Iowa, Oct. 14. Dr. Harold G. Curtis, Sunny Acres, Cuyahoga County Tuberculosis Hospital, Cleveland 22, Chairman, Program Committee.

Montana Medical Association, Baxter Hotel, Bozeman, Sept. 15-18. Mr. L. R. Hegland, P.O. Box 1692, Billings, Executive Secretary.

National Association for Mental Health, Indianapolis, Nov. 4-6. Mr. Robert M. Heininger, 1790 Broadway, New York 19, Director.

New Hampshire Medical Society, Mt. Washington Hotel, Bretton Woods, Sept. 29-Oct. 1. Dr. Warren H. Butterfield, 18 School St., Concord, Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Tex., Sept. 17. Dr. E. C. Bebb, Broad St., Wichita Falls, Tex., Chairman.

Oklahoma City Clinical Society Conference, Oklahoma City, Oct. 24-27. Dr. Charles E. Leonard, 512 Medical Arts Bldg., Oklahoma City 2, Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 24-27. Mrs. Anne K. Ramsey, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Oregon State Medical Society, Hotel Heathman, Portland, Sept. 28-Oct. 1. Dr. Richard R. Carter, 1020 S.W. Taylor St., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 18-23. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Postgraduate Assembly in Endocrinology and Metabolism, Indianapolis, Sept. 26-Oct. 1. Dr. John J. Mahoney, Assistant Dean, Indiana University School of Medicine, 1040 W. Michigan St., Indianapolis 7.

Regional Meetings, American College of Physicians:

Billings, Mont., Oct. 7-8. Dr. Harold W. Gregg, 103 North Wyoming St., Butte, Governor.

Charleston, S. C., Oct. 7-8. Dr. Robert Wilson, 165 Rutledge Ave., Charleston, S. C., Governor.

Buffalo, N. Y., Oct. 14. Dr. John H. Talbot, 100 High St., Buffalo 3, N. Y., Governor.

Madison, Wis., Oct. 15. Dr. Frederick W. Madison, 425 East Wisconsin Ave., Milwaukee 2, Governor.

Louisville, Ky., Nov. 5. Dr. Sam A. Overstreet, 332 West Broadway, Louisville, Ky., Governor.

Tennessee Valley Medical Assembly, Read House, Chattanooga, Tenn., Oct. 3-4. Dr. Harry E. Jones, 109 Medical Arts Bldg., Chattanooga 2, Tenn., Secretary.

The Constantinian Society, Sheraton-Park Hotel, Washington, D. C., Oct. 26-29. Dr. C. F. Shook, P. O. Box 1035-36, *Toledo 1, Ohio, Secretary.*

Tri-State Medical Society, Grim Hotel, Texarkana, Tex., Sept. 28-29. Dr. Karlton H. Kemp, 408 Hazel St., Texarkana, Ark., Secretary.

U. S. Chapter, International College of Surgeons, Convention Hall, Philadelphia, Sept. 12-15. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Vermont State Medical Society, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 29-Oct. 1. Dr. James P. Hammond, 337 South St., Bennington, Secretary.

Virginia, Medical Society of, Hotel Jefferson, Richmond, Oct. 16-19. Mr. Robert I. Howard, 105 West Franklin St., Richmond, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 11-14. Dr. Frederick A. Tucker, 1309 Seventh Ave., Seattle 1, Secretary.

Western Association of Railway Surgeons, Las Vegas, Nev., Sept. 22-24. Dr. Leo L. Stanley, 1322 Fifth Ave., San Rafael, Calif., Secretary.

FOREIGN AND INTERNATIONAL

Canadian Society for the Study of Fertility, Royal York Hotel, Toronto, Ont., Canada, Oct. 6-8. Dr. Earl R. Plunkett, 469 Waterloo St., London, Ont., Canada, Secretary.

International Congress of Allergology, Rio de Janeiro, Brazil, S. A., Nov. 6-13. Dr. Bernard N. Halpern, 197 boulevard St. Germain, Paris 7^e, France, Secretary General.

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. Fenton, National Research Council, Division of Anthropology and Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress of Criminology, London, England, Sept. 11-18. For information write: *Dr. Carroll, 28 Weymouth St., London, W.1,* England.

International Congress of European Society of Haematology, Freiburg i,Br., *Germany, Sept. 20-24. Prof. Dr. L. Heilmeyer, Hugstetter Strasse* 55, Freiburg i,Br., Germany, Chairman.

International Congress for the History of Science, Florence and *Milan, Italy, Sept. 3-10, 1956.* Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy, Secretary-General.

International Congress of Hydatid Disease, Athens, Greece, Sept. *14-18, 1956. Prof. B. Kourias, Croix-Rouge Hellenique, 1 rue Mac*kenzie King, Athens, Greece, Secretary-General.

International Congress of Internal Medicine, Madrid, Spain, Sept. 19-23, 1956. Dr. J. C. De Oya and Dr. J. Gimena, Hostaleza No. 90, Madrid, Spain, Secretaries.

International Congress of International College of Surgeons, Buenos Aires, Argentina, S. A., Nov. 19-24, 1956. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress of International Society of Bronchoesophagology, Buenos Aires, Argentina, S. A., Oct. 28-29. Dr. Juan Carlos Arauz, Cangallo 4015, Buenos Aires, Argentina, S. A., Secretary General.

International Congress of Librarianship and Documentation, Brussels, Belgium, Sept. 11-18. For information write: Dr. A. C. Breycha-Vauthier, Librarian, United Nations, Geneva, Switzerland.

International Congress of Medical Professional Jurisdiction, Medical Ethics, and Comparative Medical Law, Paris, France, Sept. 30-Oct. 3. Dr. J. R. DeBray, Conseil National de L'Ordre des Medécins, 60, Boulevard Latour-Maubourg, Paris 7e, France, Secretary General.

International Congress of Neo-Hippocratic Medicine, Montecatini, *Terme, Italy, May 20-22, 1956. Prof. P. Delore, 13 rue Jarenie, Lyon,* France, Secretary-General.

International Congress of Neuropathology, London, England, Sept. 12-17. Dr. W. H. McMenemey, Maida Vale Hospital for Nervous Diseases, London, W.9, England, Secretary.

International Congress of Paediatrics, Copenhagen, Denmark, July 22-27, 1956. Professor P. Plum, Rigshospitalet, Copenhagen, Denmark, President.

International Congress of Physical Medicine, Copenhagen, Denmark, August 20-24, 1956. Dr. B. Strandberg, Kobenhavns amts sygehus i Gentofte, Dept. of Rheumatology and Physical Medicine, Hellerup, Denmark, Honorable Secretary.

International Congress of Radiology, Mexico, D. F., Mexico, July 22-28, 1956. Dr. Jose Noriega, Tepic 126 (2e piso), Mexico, D. F. 7, Mexico, Secretary General.

International Congress of World Confederation for Physical Therapy, New York, New York, U. S. A., June 17-23, 1956. For information address: Miss Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York, U. S. A.

International General Medical Congress, University of Rosario Medical College, Rosario, Argentina, S. A., Nov. 7-12. Dean Jose Imhoff, Santa Fé 3100, Rosario, Argentina, S. A., Chairman.

International Physiological Congress, Brussels, Belgium, July 29-Aug. 5, 1956. For information address: Prof. J. Reuse, Faculte de Medicine et de Pharmacie, 115 Boulevard de Waterloo, Brussels, Belgium.

International Professional Union of Gynecologists and Obstetricians, Madrid, Spain, Sept. 28-29, 1956. Dr. Jacques Courtois, 1 rue Racine, St-Germain-en-Laye (S and O), France, Permanent International Secretary-General.

International Society for the Study of Biological Rhythms, Stockholm, Sweden, Sept. 15-17. For information write: Prof. Ture Petrén, *Karolinska Institutet, Stockholm 60, Sweden.*

Medical Journalism Meeting, Vienna, Austria, Sept. 23. For information address: World Medical Association, 345 East 46th St., New York, N. Y., U.S.A.

Neuroradiologic Symposium, London, England, Sept. 13-17. Dr. R. D. Hoare, National Hospital, Queen Square, London, W.C.1, England, Secretary.

North Queensland Medical Conference, Cairns, North Queensland, Australia, June 25-30, 1956. Dr. W. R. Horsfall, P. O Box 672, Cairns, N.Q., Australia, Secretary.

Pan American Congress of International College of Surgeons, Mendoza City, Argentina, S. A., Oct. 22-26. For information address: Secretary, Caseros Av. 2154, Buenos Aires, Argentina, S. A.

Pan American Congress of Ophthalmology, Santiago, Chile, S. A., Jan. 9-14, 1956. Dr. Rene Contardo, Huerfanos 930, Of. 74, Santiago, Chile, Secretary General.

Pan American Medical Social Convention, Bogota, Colombia, S. A., Oct. 15-22. Dr. Leopoldo E. Araujo, Avenida de los Presidentes Num. *506, Apartado 2589,* La Habana, Cuba, *Secretary.*

Pan American Medical Women's Alliance, Santiago, Chile, March 6-13, 1956. For information address: Dr. Eva Cutright, 458 Beall Ave., *Wooster, Ohio, U. S. A.*

Venezuelan Congress of Medical Sciences, Caracas, Venezuela, S. A., Nov. 18-26. Dr. A. L. Briceno Rossi, Apartado 4412, Ofic. del Este, *Caracas, Venezuela, S. A.,* Secretary General.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

World Medical Association, Vienna, Austria, Sept. 20-26. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 19-21. Sec., Dr. D. G. Gill, *State Office Bldg., Montgomery.*

Arizona:* *Examination.* Phoenix, Oct. 12-14. *Reciprocity.* Phoenix, Oct. 15. Exec. Sec., Mr. Robert Carpenter, 411 Security Bldg., Phoenix.

Arkansas:* *Examination.* Little Rock, Nov. 10-11. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Sacramento, Oct. 17-20. *Oral and Clinical Examinations for Foreign Medical School Graduates.* San Francisco, Nov. 13. *Oral Examination for Reciprocity Applications.* San Francisco, Nov. 12. Sec., Dr. Louis E. Jones, Room 536, 1020 N St., Sacramento.

Colorado:* *Examination.* Denver, Dec. 6-7. Final date for filing application is Nov. 4. *Reciprocity.* Denver, Oct. 11. Final date for filing application is Sept. 12. Exec. Sec., Mrs. Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* Hartford, Nov. 8-10. Sec., Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic.* Derby, Nov. 8-19. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Examination.* Dover, Jan. 10-12. *Reciprocity.* Dover, Jan. 19. Sec., Dr. Joseph S. McDaniel, Dover.

Florida:* *Examination.* Miami Beach, Nov. 20-21. Sec., Dr. Homer L. Pearson, 901 N. W. 17th St., Miami.

Georgia: *Examination.* Atlanta, Oct. 5-6. *Reciprocity.* Atlanta, Oct. 7. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Idaho: *Examination and Reciprocity.* Boise, Jan. 9-11. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity.* Chicago, Oct. 11-13. Supt. of Registration, Mr. Fredric B. Selcke, State House, Springfield.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Kansas: *Examination and Endorsement.* Topeka, Dec. 7-8. Sec., Dr. Lyle F. Schmaus, New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 5-7. Asst. Sec., Mr. R. F. Dixon, 620 S. 3rd St., Louisville.

Maine: *Examination and Reciprocity.* Portland, Nov. 8-9. Sec., Dr. Adam P. Leighton, Portland.

Maryland: *Examination.* Baltimore, Dec. 13-16. Exec. Sec., Miss Hannah A. McCarthy, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Lansing, Oct. 12-14. Sec., Dr. J. Earl McIntyre, 118 Stevens T. Mason Bldg., Lansing.

Minnesota:* *Examination and Reciprocity.* Minneapolis, Oct. 18-20. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Missouri: *Examination and Endorsement.* St. Louis, Oct. 21-22. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Montana: *Examination and Reciprocity.* Helena, Oct. 4-5. Sec., Dr. Sidney A. Cooney, 7 West 6th Ave., Helena.

Nebraska:* *Examination.* Omaha, June 18-20. Director, Bureau of Examining Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* *Examination and Reciprocity.* Reno, Oct. 4. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: *Examination and Reciprocity.* Concord. Sept. 14. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 18-21. Sec., Dr. Patrick H. Corrigan, 28 W. State St., Trenton.

New Mexico:* *Examination and Reciprocity.* Santa Fe, Nov. 21-22. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York City and Syracuse, Oct. 4-7. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity.* Asheville, Oct. 31. Sec., Dr. Jos. J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 4-6. *Reciprocity.* Grand Forks, Jan. 7. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

Ohio: *Reciprocity.* Columbus, Oct. 4. *Examination.* Columbus, Dec. 15-17. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma:* *Endorsement.* Oklahoma City, Sept. 4. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Reciprocity.* Portland, Oct. 13-15. *Examination.* Portland, January. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia, January. Acting Sec., Miss Marguerite G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination.* Providence, Oct. 6-7. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination.* Columbia, Nov. 7. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Jan. 17-18. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Sept. 28-29. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Texas:* *Examination and Reciprocity.* Galveston, Dec. 1-3. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Virginia: *Examination.* Richmond, Dec. 7-9. *Reciprocity.* Richmond, Dec. 6. Final date for filing application is Nov. 21. Address the Secretary, 631 First St. S.W., Roanoke.

West Virginia: *Reciprocity.* Charleston, Oct. 10. Sec., Dr. N. H. Dyer, Charleston 5.

Wisconsin:* *Reciprocity.* Madison, Oct. 21. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

Wyoming: *Examination.* Cheyenne, Oct. 3. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

Alaska:* On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Sec., Dr. John E. Kennedy, Agana.

Hawaii: *Examination.* Honolulu, Jan. 9-12. Sec., Dr. I. L. Tilden, 1020 Kapiolani, St., Honolulu.

Virgin Islands: *Examination and Endorsement.* St. Thomas, Nov. 8-9. Sec., Dr. Earle M. Rice, St. Thomas.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, Sept. 20. Sec., Dr. H. D. Rhodes, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 4. Sec., Dr. S. C. Dellinger, Zoology Dept., University of Arkansas, Fayetteville.

Colorado: *Examination.* Denver, Sept. 7-8. Final date for filing application is Aug. 24. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination.* New Haven, Oct. 8. Address: State Board of Healing Arts, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 24-25. Deputy, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington 6.

Florida: *Examination.* Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, Box 340, Gainesville.

Iowa: *Examination.* Des Moines, Oct. 11. Sec., Mr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination and Endorsement.* Detroit and Ann Arbor, Oct. 14-15. Sec., Mrs. Anne Baker, 410 W. Michigan Ave., Lansing 15.

Minnesota: *Examination.* Minneapolis, Oct. 4-5. Sec., Mr. Raymond N. Bieter, 126 Millard Hall, University of Minnesota Campus, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 4-5. Director, Bureau of Examining Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada: *Examination.* Reno, Oct. 4. Sec., Dr. Donald G. Cooney, Box 9005, University of Nevada, Reno.

Oregon: *Examination.* Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

South Dakota: *Examination.* Vermillion, Dec. 2-3. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination.* Memphis, Sept. 22-23. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

Texas: *Examination.* Austin and Houston, Oct. 21-22. Sec., Brother Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 23; Milwaukee, Dec. 3. Sec., Mr. William H. Barger, 621 Ransom St., Ripon.

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of The Journal. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Sept. 12

NBC-TV, 9 p. m. EDT. "Medic" presents "Walk with Lions."

ABC-TV, 9:30 p. m. EDT. "Medical Horizons" inaugurates a weekly series of programs with a live remote pickup from the Mayo Clinic. Subject will be the heart-lung bypass. Presented in cooperation with the American Medical Association.

Wednesday, Sept. 14

NBC-TV, 11:30 a. m. EDT. "Medical and Health News with Howard Whitman," a part of the "Home" program.

MAGAZINES

Saturday Evening Post, Sept. 3, 1955

"Surgery Restored My Sight," by Paul W. Kearney

A personal experience story combined with factual information on the surgical removal of cataracts.

The American Magazine, September, 1955

"Man in the Middle," by Clarence Woodbury

The story of Basil O'Connor and his work with the National Foundation for Infantile Paralysis. One paragraph says: "Organized doctors, fearing that O'Connor's practice of paying the bills of polio patients was a step toward socialized medicine, took a slap at him, too. When it was proposed to the American Medical Association that an award be granted to O'Connor as a non-doctor who had made big contributions to medicine, the proposal was voted down."

Redbook, September, 1955

"We Saved the Lives of 22 Children," by Llewellyn Miller

How the town of Gary, Ind., mobilized to treat residents bitten by rabid dogs and prevented the spread of the disease.

Family Weekly Magazine, Sept. 3, 1955

"How to Master Your Fears," by Dr. Franz Alexander and Francesca Alexander

If people with anxieties and fears need special help in solving their problems, the author recommends they consult an expert. Among those lis.ed are the family doctor and a psychiatrist.

GOVERNMENT SERVICES

ARMY

Colonel Glattly Promoted to Brigadier General.—On the eve (July 28) of becoming surgeon of the First Army, Col. Harold Glattly was promoted to brigadier general at a ceremony presided over by Major Gen. Silas B. Hays, the surgeon general. General Glattly will have his headquarters on Governors Island in New York City. For the past four years he has been chief of the personnel division in the surgeon general's office. General Glattly was a prisoner of the Japanese from April 9, 1942, to Sept. 6, 1945. He has been awarded, among others, the Bronze Star, the Asiatic-Pacific medal, the Legion of Merit, the Army Commendation Ribbon, and the Silver Star with Oak Leaf Cluster.

NAVY

New Senior Medical Student Program Offered.—Medical students commissioned as ensigns 1995, U. S. N. R., and about to enter their final year of medical school are eligible to apply for the new ensign 1995 senior medical student program that permits the Navy to sponsor education for medical students who have selected the Navy as the service of their choice. Candidates must meet the following requirements: (*a*) be commissioned an ensign 1995 (medical) U. S. N. R., (*b*) be accepted for enrollment in a school of medicine accredited by the American Medical Association, (*c*) meet the physical standards established for regular Navy staff corps officers, (*d*) on completion of medical school agree to accept a regular Navy commission, and, if a regular commission is not tendered, accept a commission in the Naval Reserve, (*e*) agree to participate in the National Intern Matching Plan. In the event the individual is not matched with the Navy, he must accept a superseding appointment in the Naval Reserve and will be in an inactive status while completing a civilian internship not to exceed 12 months. On completion of this internship, a regular commission must be accepted if tendered. Ensign 1995 (medical) officers, if selected, will be ordered to active duty at the medical school where enrolled, and, while in attendance and successfully pursuing their professional studies will receive the full pay and allowance of their rank.

Pay and allowances are based on longevity as follows: (*a*) less than two years and no dependents—$338.58 per month; with dependents, $355.68 per month, (*b*) over two but less than three years and no dependents—$353.40 per month; with dependents, $370.50 per month, (*c*) over three but less than six years and no dependents—$412.68 per month; with dependents, $429.78 per month, (*d*) over six but less than eight years and no dependents—$428.28 per month; with dependents, $445.38 per month. Ensigns 1995 availing themselves of this senior medical student training and accepting an appointment in the regular Navy will be obligated to serve on active duty at the discretion of the Secretary of the Navy for a minimum period of three years excluding the period served as a senior medical student and in an internship. Applications are currently being processed at all recruiting stations and offices of naval officer procurement, where more detailed information may be obtained.

Personal.—Rear Adm. H. Lamont Pugh, M. C., former surgeon general of the Navy, reported to the Bureau of Medicine and Surgery on Aug. 12 for duty as inspector general of medical department activities, relieving Rear Adm. James R. Fulton, who has been ordered to duty as district medical officer, fourth naval district.——Capt. John Philip Brady and Capt. Arthur William Loy, M. C., were placed on the retired list on Aug. 1. Capt. Brady had more than 30 years of service in the Naval Medical Corps, and Capt. Loy had more than 29 years of service.

PUBLIC HEALTH SERVICE

Poliomyelitis Vaccine.—The Public Health Service has announced the allotment of funds to each state under the 30 million dollar poliomyelitis vaccine assistance act signed Aug. 12 by President Eisenhower. The new law apportions the money in accordance with a formula involving the number of unvaccinated children under age 20 and expectant mothers in each state, the relative per capita income of the state, and the per capita cost of vaccine. Of the 30 million dollars that Congress appropriated, 25 million dollars is available only for the purchase of vaccine and 5 million dollars may be used for the costs of planning and conducting poliomyelitis immunization programs or for the purchase of vaccine. The funds are to be used by Feb. 15, 1956. Under the law a single official agency in each state will be designated for the program and will submit a plan to the Public Health Service when applying for its allocated payment. While permitting the use of this vaccine by private physicians and by nonprofit organizations as well as by public agencies, the law provides that in vaccination programs conducted by public agencies no "means test" may be used to limit eligibility. The law restricts the use of vaccine purchased with these funds to pregnant women and to children under 20. The poliomyelitis vaccine assistance act is separate from the voluntary plan that went into effect July 31 for allocation of the vaccine during the period of short supply. Under the voluntary allocation plan, the Public Health Service allocates the supply.

The release and allocation of 1,177,000 cc. of poliomyelitis vaccine to the states and territories was announced Aug. 9 by the Public Health Service. It is the second allocation of new vaccine under the voluntary control plan for the vaccine. Under the voluntary control plan, this allocation, like the first, will be distributed in the states through both public agencies and to private physicians through normal commercial drug channels. The share that each state receives is governed by the state's proportion of unvaccinated children in the 5 through 9 year age group, which is the current priority group. Each state decides how much of its share it will distribute through public agencies and how much through commercial channels. In addition to the 1,177,000 cc., which was produced by the Wyeth Laboratories, Inc., the Public Health Service also announced the release of some 287,000 cc. produced by the Pitman-Moore Company, which the company will make available to the National Foundation for Infantile Paralysis for use in its program of immunization of first and second graders.

The Food and Drug Administration will hire 48 temporary investigators to enforce the federal prescription drug law against possible "black market" distribution of the Salk poliomyelitis vaccine. The activities of the FDA will be carried out in connection with the voluntary plan for allocation of the vaccine. An appropriation of $300,000 was made by Congress in order to cover the expenses of this special FDA program. The 48 special investigators will check on the distribution of the vaccine for the purpose of accounting for all of the vaccine that is made or shipped. Such checkups will be considered complete in regard to any particular lot of vaccine when the FDA has a record indicating its total distribution into legal channels; i. e., when it has been determined that the vaccine is in the hands of a physician, a hospital, a state or local health department, or other authorized persons or agencies.

Immunization for Foreign Travel.—A supplement to the booklet "Immunization Information for International Travel," recently released by the Public Health Service, carries changes in immunization requirements from June, 1954, to June, 1955. Persons having a 1954 edition of the booklet may obtain copies of the supplement, free of charge, from the U. S. Public Health Service, Division of Foreign Quarantine, Washington 25, D. C. The booklet, including the new supplement, may be purchased for 20 cents from Superintendent of Documents, Government Printing Office, Washington 25, D. C. A 25% discount is allowed on orders of 100 copies or more delivered to the same address.

DEATHS

Fein, Maxwell Janeway ⊕ New York City; born May 18, 1894; Long Island College Hospital, Brooklyn, 1917; specialist certified by the American Board of Pathology; instructor of pathology at the Bellevue Hospital Medical School from 1922 to 1926; clinical professor of pathology at the New York Post Graduate Medical School and Hospital, Columbia University, from 1942 to 1947; clinical professor of pathology at the New York University College of Medicine and the New York Post-Graduate Medical School; visiting professor of pathology at Rutgers University in New Brunswick, N. J., from 1949 to 1951, and visiting professor of pathology at Seton Hall University, South Orange, N. J., since 1948; a founder of the Blue Shield movement in New York, and a vice-president of the United Medical Service; founding fellow, governor, and member of the executive committee of the College of American Pathologists; fellow of the American Society of Clinical Pathologists; member of the World Medical Association, New York Academy of Sciences, and the American Public Health Association; since 1938 secretary-treasurer of the New York State Society of Pathologists; secretary of the section on pathology and clinical pathology of the Medical Society of the State of New York; in charge of Army hospital laboratories during World War I; on advisory committees on State Nurse and Professional Placement, New York City Community College of Applied Arts and Sciences, and the committee on cancer and results of the American Cancer Society; director of laboratories, Broad Street Hospital in New York City, from 1919 to 1928, Mountainside Hospital in Montclair, N. J., from 1928 to 1943, Madison Park Hospital in Brooklyn, from 1928 to 1940, Unity Hospital, Brooklyn, since 1928, where he was consultant pathologist, Adelphi Hospital in Brooklyn, from 1932 to 1949, serving as consultant pathologist, and the Murray Hill Hospital in New York City from 1940 to 1947; from 1920 to 1928 pathologist at the Cumberland Hospital in Brooklyn and the Brooklyn Cancer Hospital; director of the laboratory at the Wickersham Hospital since 1935, Shore Road Hospital since 1930, and director and owner of Laboratories of Dr. M. J. Fein since 1928; at the time of his death consultant pathologist at the Morristown (N. J.) Hospital, Princeton (N. J.) Hospital, South Nassau Communities Hospital, Rockville Centre, Veterans Administration Regional Office, and the Esso Standard Oil Company; died in the New York Hospital July 14, aged 61, of cancer of the lung.

Meeker, William Raymond ⊕ Mobile, Ala.; born in Hazel Dell, Ill., June 2, 1889; Rush Medical College, Chicago, 1920; interned at the Cook County Hospital in Chicago; served as instructor in anatomy at the University of Chicago, assistant professor of pathology at Loyola University in Chicago, and professor of pathology at the University of Arkansas in Little Rock, where he was medical director of the City Hospital; spent four years as staff member at the Mayo Clinic, Rochester, Minn., after which he was assistant professor of surgery at the University of Illinois College of Medicine in Chicago; certified by the National Board of Medical Examiners; member of the founders group of the American Board of Surgery; fellow of the International College of Surgeons and the American College of surgeons; past-president, Gulf Coast Clinical Society; active member of the Southeastern Surgical Congress and the Southern Medical Association; past-president of the staffs of the Mobile Infirmary, Providence Hospital, Mobile City Hospital, and Blessed Martin de Porres Hospital; captain in the Medical Corps of the U. S. Naval Reserve during World War II; died July 22, aged 66, of coronary occlusion.

Barkoff, Samuel ⊕ New Orleans; born in New Orleans Nov. 26, 1912; Tulane University of Louisiana School of Medicine, New Orleans, 1934; served on the faculty of his alma mater; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychoanalytic Association and the American Psychiatric Association; president-elect of the New Orleans Psychoanalytic Society; consultant for the department of public welfare for the state of Mississippi and consultant for the division of vocational education of Louisiana State Department of Education; on the staff of the Touro Infirmary; died July 11, aged 42.

Kowalski, Henry John ⊕ Seattle; born in Grand Rapids, Mich.; July 2, 1916; University of Michigan Medical School, Ann Arbor, 1944; specialist certified by the American Board of Internal Medicine; certified by the National Board of Medical Examiners; served with the Army Medical Corps in Korea; interned at the Massachusetts General Hospital in Boston, where he served a residency at the Boston City Hospital; instructor in medicine at Harvard Medical School from 1951 to 1953; on the faculty at the University of Washington Medical School; a staff member of the Swedish, Providence, Doctors, and King County hospitals and the Veterans Administration Hospital, where he died July 20, aged 39, of pulmonary artery thrombosis.

Lorenz, Thomas Holt ⊕ Madison, Wis.; born in Madison Feb. 26, 1920; University of Wisconsin Medical School, Madison, 1944; interned at the Evanston Hospital in Evanston, Ill.; formerly a resident at the State of Wisconsin General Hospital in Madison and the New York Hospital in New York City; assistant professor of medicine at his alma mater; lieutenant colonel in the National Guard and commander of the 135th medical battalion; during a three year service period in the Medical Reserve Corps of the U. S. Army was stationed in the European theater of operations for 18 months during the German occupation; died in Camp McCoy, Sparta, June 16, aged 35, of coronary occlusion.

Friedman, Arnold Leo ⊕ Rockville Centre, N. Y.; born in New York City Aug. 27, 1917; University of Michigan Medical School, Ann Arbor, 1942; specialist certified by the American Board of Surgery; affiliated with the Meadowbrook Hospital in Hempstead, where he served an internship; served a residency in pathology at the New York Post Graduate Medical School and Hospital in New York City and in surgery at the Mount Sinai Hospital in Cleveland; on the staffs of the Mercy and South Nassau Communities hospitals; served during World War II; died in the Long Island College Hospital, Brooklyn, July 31, aged 37, of a brain tumor.

Aitkens, Herbert Baber ⊕ Le Center, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1893; member of the school board; served on the staff of St. Joseph's Hospital in Mankato; died June 6, aged 88, of senility.

Bentley, Neil Isaac ⊕ Detroit; University of Michigan Homeopathic Medical School, Ann Arbor, 1906; on faculty of Detroit Homeopathic Medical College; specialist certified by American Board of Ophthalmology and American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; consultant on the staffs of the Florence Crittenden Hospital and Grace Hospital, where he died June 22, aged 73, of coronary thrombosis.

Bernard, C. Henry ⊕ Cleveland; University of Kansas School of Medicine, Kansas City, Kan., 1930; served during World War II; interned at St. Alexis Hospital; on the staff of the Children's Hospital in Akron, where he was formerly a resident in the City Hospital; died May 20, aged 52, of coronary heart disease.

Blackwelder, Glenn Elvin ⊕ Chico, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1947; served during World War II; died June 23, aged 34, of pneumonia.

Bolin, Herbert Julian ⊕ Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1915; past-president of the Knox County Medical Society; died in Fort Sanders Hospital May 12, aged 66, of primary pulmonary emphysema.

⊕ Indicates Member of the American Medical Association.

Brown, Hugo Otto, Magnolia Springs, Ala.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1910; died in Mobile July 10, aged 67, of coronary occlusion.

Bunshaw, Albert Hudson ⊕ Erie, Pa.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909; for many years on the staff of St. Vincent's Hospital; died June 29, aged 74, of a heart attack.

Burkhart, Victor H. ⊕ Hurst, Ill.; Chicago College of Medicine and Surgery, 1910; served as mayor; died in the Doctors Hospital, Carbondale, July 27, aged 72, of coronary disease.

Carr, Joseph Thompson ⊕ Moselle, Miss.; Kentucky University Medical Department, Louisville, 1905; died in Methodist Hospital, Hattiesburg, Aug. 5, aged 80.

Cavanaugh, Leo Martin, Takoma Park, Md.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1913; past-secretary of the Allegany County Medical Society; served during World Wars I and II; for many years consultant for the Veterans Administration; died in Mount Alto Veterans Administration Hospital, Washington, D. C., July 16, aged 67, of cancer.

Champion, William Leon ⊕ Atlanta, Ga.; College of Physicians and Surgeons, Baltimore, 1891; fellow of the American College of Surgeons; served as first president of the Atlanta and Georgia Urological Society; past-president of the Fulton County Medical Society; for many years on the staff of St. Joseph's Hospital; died July 2, aged 86.

Cochran, Charles Edgar, St. Louis; American Medical College, St. Louis, 1903; died in the Park Lane Hospital April 25, aged 75, of cerebral hemorrhage.

Comroe, Julius Hiram Sr. ⊕ York, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; an associate member of the American Medical Association; on the staff of the York Hospital; died in the Hospital of the University of Pennsylvania, Philadelphia, July 16, aged 73, of coronary occlusion.

Dewees, Jacob Highley, New York City; University of Pennsylvania Department of Medicine, Philadelphia, 1894; member of the Medical Society of the State of New York; died in the Veterans Administration Hospital, Bath, April 5, aged 85, of lobar pneumonia.

Elmer, Florence Dudley Greaves, Portland, Ore.; University of California Medical School, San Francisco, 1934; died in the Good Samaritan Hospital July 10, aged 46, of pulmonary edema and rheumatic heart disease.

Ford, Walter Ari ⊕ Houston, Texas; Bennett Medical College, Chicago, 1913; on the faculty of Baylor University College of Medicine; served during World Wars I and II; on the staff of the Jefferson Davis Hospital; died July 12, aged 68, of coronary occlusion.

Goldberg, Sidney, Chicago; University of Illinois College of Medicine, Chicago, 1952; following his internship at the Cook County Hospital, served a residency in pediatrics at the Louisville General Hospital and the Children's Hospital in Louisville, Ky.; died in the Albert Merritt Billings Hospital July 31, aged 29, of Hodgkin's disease.

Green, William L. Sr., Lexington, Ga.; Southern Medical College, Atlanta, 1887; died in Athens May 23, aged 91, of dissecting aneurysm of the aorta, arteriosclerosis, and diabetes mellitus.

Grinnell, Wendell B., Preston, Minn.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; died May 30, aged 82, of cerebral hemorrhage.

Hammel, Seth A. ⊕ Topeka, Kan.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; veteran of the Spanish-American War; served during World War I; medical officer of the state selective service during World War II; formerly on the faculty of the Kansas Medical College, Medical Department of Washburn College; died July 28, aged 76.

Harrington, Richard ⊕ Williamsville, N. Y.; Trinity Medical College, Toronto, Canada, 1901; an associate member of the American Medical Association; served on the staffs of Millard Fillmore, Edward J. Meyer Memorial, and Sisters of Charity hospitals in Buffalo; formerly director of Bank of Williamsville; died in Clarence July 5, aged 82, of coronary disease.

Henes, Edwin Jr. ⊕ Milwaukee; Columbia University College of Physicians and Surgeons, New York City, 1910; died July 25, aged 70, of arteriosclerosis.

Hibbard, Burt ⊕ Lima, Ohio; University of Buffalo School of Medicine, 1900; at one time vice-president of the Northern Tri-State Medical Association; formerly an officer in the regular Army; served during World War I; at one time county coroner; died in the Veterans Administration Hospital in Marion, Ind., July 18, aged 78, of bronchial pneumonia.

Hollinshead, Theodore Highbee ⊕ Louisville, Ky.; Hahnemann Medical College and Hospital of Philadelphia, 1898; an associate member of the American Medical Association; died May 29, aged 95, of pulmonary edema.

Horton, Logan Warren, New Orleans; Howard University College of Medicine, Washington, D. C., 1927; died in the Veterans Administration Hospital, Tuskegee, Ala., May 5, aged 57, of cancer of the stomach.

Iseri, Kawor, Los Angeles; Cooper Medical College, San Francisco, 1912; died July 23, aged 76, of cerebral thrombosis.

Jackson, Ransome Otha, Savannah, N. Y.; Rush Medical College, Chicago, 1928; health officer for the village and town of Savannah; from 1943 to 1954 also health officer of the town of Tyre, Seneca County; chief of staff of Lyons (N. Y.) Hospital; on the staffs of the Auburn Memorial and Mercy hospitals in Auburn; died June 12, aged 59, of coronary thrombosis.

James, Frederick Weiss, Norfolk, Va.; Leonard Medical School, Raleigh, N. C., 1906; died May 25, aged 74, of myocardial infarction.

Johnson, John Birger Albert ⊕ Lowell, Mass.; Tufts College Medical School, Boston, 1908; served during World War I; at one time on the school board; died in the Shaw Hospital July 6, aged 76, of a cerebral vascular accident.

Johnston, Lawrence Walton ⊕ Terrell, Texas; Baylor University College of Medicine, Dallas, 1938; formerly city health officer; member of the American Academy of General Practice; councilor of the 14th medical district of Texas, of which he was formerly secretary-treasurer; past-president and secretary of the Kaufman County Medical Society; interned at the Shreveport (La.) Charity Hospital; on the staffs of the Holton-Johnston Hospital and Terrell State Hospital; died in Falls Church, Va., May 15, aged 45, of coronary occlusion.

Kaley, Clifford Matthew ⊕ Caldwell, Idaho; Northwestern University Medical School, Chicago, 1904; on the staff of the Caldwell Memorial Hospital, where he died May 25, aged 77, of cancer.

Keating, Charles Albert ⊕ Paterson, N. J.; Jefferson Medical College of Philadelphia, 1902; served during World War I; died in the Paterson General Hospital July 17, aged 80, of pulmonary embolism.

Leake, Norman Augustus ⊕ Torrance, Calif.; Medical Department of the University of California, San Francisco, 1912; an associate member of the American Medical Association; served during World War I; draft board medical examiner during World War II; on the staff of the Jared Sidney Torrance Memorial Hospital; died in Long Beach July 6, aged 78, of cerebral arteriosclerosis.

Lester, David Howard Russell ⊕ Schenectady, N. Y.; Albany (N. Y.) Medical College, 1929; interned at the Ellis Hospital, where he was on the courtesy staff; formerly a resident in surgery at the Bellevue Hospital in New York City; on the courtesy staff of St. Clare's Hospital; died June 4, aged 50, in an airplane accident.

McGrath, Maurice James ⊕ Oswego, N. Y.; Albany (N. Y.) Medical College, 1911; past-president of the Oswego Academy of Medicine; from 1940 to 1950 assistant health officer of Oswego; on the staff of the Ellis Hospital in Schenectady; an emeritus member of the staff of the Oswego Hospital, where he died May 28, aged 72, of heart disease.

BELGIUM

Acute Digestive Hemorrhages.—At a meeting of the Belgian Surgical Association in May, Moyson and de Scoville stated that in hemorrhages from the upper gastrointestinal tract peptic ulcers (chiefly duodenal) accounted for 70%, esophageal varices and gastritis for 10 to 20%, gastric carcinoma for 4%, hiatus hernias and other esophageal disorders for 10%, and an indeterminate group for the rest. Diagnostic methods need to be improved. Ulcers have a definite antecedent history in 75% of the patients. The gastric juice shows achlorhydria when there is a bleeding ulcer. Emergency radiological examination is useful, not dangerous, and can reveal the coexistence of such lesions as a peptic ulcer and esophageal varices, an ulcer and hiatus hernia, or hiatus hernia and diverticulum. If hepatic cirrhosis is suspected, a transparietal splenoportogram should be made. Prior radiographic examination, if it is negative, may make it impossible to interpret the films because some barium may be left in the digestive tract. A film showing hypertension of the portal system gives no information as to the source of the hemorrhage.

If the patient has an ulcer and esophageal varices, the problem is not resolved, although the ulcer is more frequently the source of the hemorrhage. In such patients the installation of a balloon tube gives the differential diagnosis, because either the hemorrhage stops or blood may be aspirated from the stomach. Esophagoscopy is dangerous. The bromsulphalein test gives information on the liver function but tells nothing about the source of the hemorrhage. It is important to determine the age of an ulcer because a recent ulcer still has normal arterial walls while an older lesion is accompanied by endarteritis. Multiple ulcers can cause massive hemorrhages. They usually follow an aggressive emotional outburst, which liberates corticotropin and causes hypersecretion with an increase in hydrochloric acid and pepsin. Esophageal varices bleed either because of thinning of the covering epithelium, which bursts abruptly, or peptic erosions resulting from regurgitation of gastric secretion and weakening of the esophageal epithelium by stasis anoxia.

Ulcers should be treated by discontinuous gastric aspiration, intragastric injections of thrombin, antacids, and blood transfusion. Transfusions have reduced the number of patients requiring operation and increased the number who can withstand surgical intervention. All patients over 50 with an ulcer of more than six months duration should be operated on immediately, and all patients with ulcer, regardless of their age, who have recurrence of hemorrhage within 48 hours or who continue to bleed during their hospitalization should be operated on. This also holds for patients with hemorrhagic gastritis. In patients with hemorrhage from esophageal varices, a Sengstaken-Blakemore tube should be passed and the patient rapidly and abundantly transfused. Splenoportography performed after shock has been controlled will establish whether the block is intrahepatic or extrahepatic.

If the patient has cirrhosis and hemorrhage is not controlled within 24 hours, transesophageal ligation of the varices, which is always effective, or simple ligation of the splenic artery, which is often effective, is required. In the case of extrahepatic block after the hemorrhage is temporarily controlled, splenectomy and splenorenal anastomosis or esophagogastrectomy may be performed. The latter is the only rational treatment in a patient who has already had a splenectomy or who has an associated esophageal peptic ulcer and varices. In cirrhotic patients ligation of the varices should be accompanied by portacaval anastomosis or arterialization of the portal blood. When exploratory operations are performed the portal pressure should be measured by means of a nylon catheter inserted into an epiploic vein. This benign procedure eliminates the possibility of portal hypertension, or, if this exists, of substituting direct ligation of the splenic artery for a blind gastrectomy that is without effect.

Determining Blood Alcohol.—At a meeting of the Belgian Legal Medicine Society in April, Professor Labarre and Mrs. Hans reported that blood alcohol levels may be determined by chemical, physical, or physicochemical methods. Factors to be considered are the ratio between alcohol ingested and eliminated, per hour and per kilogram of body weight; the distribution of the toxic agent in the various organs of the body; variations due to sex; and individual characteristics. To be valid, the analysis must be made under certain prescribed conditions. Whole blood must be used. The optimal time for obtaining the blood sample is 90 minutes after the last ingestion of alcohol. Professor Labarre believes the lowest blood alcohol level that may be said to contribute to causing an automobile accident is 0.12%. The amount of liquor that must be consumed for this rate to be reached depends on the weight of the consumer, whether the alcohol is consumed on an empty stomach, the condition of the subject's liver and kidneys, whether he has glycosuria, his tolerance to alcohol, and such substances that may have been ingested simultaneously as antihistamines and barbiturates.

Laws on Alcohol Consumption.—The National Committee Against Alcoholism has published a pamphlet: "Reflections on the Law in Relation to Alcohol Consumption." The present law prohibiting the sale of alcohol in quantities less than two liters and the dispensing of alcoholic beverages in public places, although still in effect, is not strictly observed. Present statistics on the consumption of beer and spirits prove that this legislation prevents the massive consumption of distilled beverages in public. The brochure insists that the prohibition on consuming and dispensing spiritous liquors in all public places be maintained. The National Committee is affiliated with most health and youth organizations and subscribes to the categorical pronouncements of the Royal Academies of Medicine, the Belgian Neurological Society, the Psychiatric Society, the National League of Public Morality, and the National Council of Belgian Women. The present laws on the consumption of alcohol are susceptible to improvements, but to weaken them would be to expose the population to serious dangers.

Radiological Hazards.—Dr. Bacq, in an address to the Belgian Society of Radiology, said that geneticists admit the possibility of a genetic hazard if the basal level of radioactivity of the earth be raised through the intensive use of atomic energy. All possible sources of ionizing radiation should be rigidly controlled. In particular, radiologists ought to: (1) check the output of their apparatus and make sure they use machines that give satisfactory information with the minimum dosage of x-rays, even if such machines are more expensive; (2) take steps to avoid irradiation of the gonads during examinations of the digestive tract, bladder, and colon, at least in persons of procreating age; and (3) use physiological radioprotectors of the cysteine or cystine type to eliminate direct and indirect effects, especially on the bone marrow and adrenals.

Health of Miners.—The government has enacted a new safety measure for the benefit of mine workers. All persons applying for this work must have microscopic examination of their stools for hookworm ova. The examination will be carried out during the 40 days preceding the date these persons are to start working, and they can have access to the underground works only if the results of their examination are negative. The examination will be performed twice, once between the 30th and 40th days, and again between the 90th and 100th days after the first examination. The examinations may be performed only by physicians appointed by the Ministry of Public Health. It is the employers' responsibility to see that this program is carried out and kept up to date.

The items in these letters are contributed by regular correspondents in the various foreign countries.

CHILE

Diabetic Survey.—Writing in the January issue of the *Revista médica de Chile*, Prof. D. Urrutia and his co-workers review their experience with 1,396 diabetic patients. The age when the disease was discovered was between 41 and 60 years in 65%; in only 7% was the disease discovered before the age of 30; and in 9% it was discovered after 60. In 14% the diagnosis was made only through a blood sugar determination performed during a regular health examination. Only 44% of the patients consulted a physician in the first year of their disease. Severe alcoholism was found in only 5%, which corresponds to the incidence of alcoholism in the general population. The diabetes began as a consequence of acute pancreatitis in only six patients. Body weight was normal at the beginning of treatment in 46%; obesity was present in 37%; and 17% were underweight. Only 29 had hypertension. In 40% the only treatment required was dietetic; 35% required an average of 40 units of insulin a day; 20% required 20 to 30 units daily; and 5% required more than 50 units per day. Severe hypoglycemic reactions occurred in only 24 patients. In 82% of the patients the course of the disease was benign, and in the rest it was severe because of complications or the intensity of the metabolic process. Acidosis and coma were present in 43 patients and were responsible for the death of 5. Vulvar pruritus was present in 37%, balanitis in 0.86%, pyorrhea in 11%, and furunculosis in 2.3%. Coronary arteriosclerosis was present in 20 patients, cerebral vascular accidents in 13, intermittent claudication in 22, gangrene in 10, polyneuritis in 34, and albuminuria in 25. Typical diabetic retinitis was seen in 152 of 422 patients examined with the ophthalmoscope. Sexual impotence was present in only four patients. Diabetes and pulmonary tuberculosis were associated in 7%. Pregnancy, present in 13 patients, was found to aggravate the symptoms of diabetes only moderately. The authors concluded that, in those patients in whom the disease started before the age of 40, the percentage of severe cases was greater than in the elder group. If the onset is rapid the prognosis is worse than if it is slow or asymptomatic. Men more frequently had severe forms than women, and the disease was more severe in patients who were underweight at the first consultation than in those in whom the weight was normal.

Viral Hepatitis.—Prof. R. Armas Cruz and his co-workers, in the *Revista médica de Chile* for February, report a series of 275 patients with viral hepatitis. Of these 62.2% were between 15 and 24 years of age. The highest incidence occurred in the summer. In 16.3% of the patients there was a history of blood transfusions or intravenous injection. The onset was sudden in 35%. Abdominal distress was the symptom most frequently present (44%) followed by such gastrointestinal disturbances as nausea, vomiting, diarrhea, or constipation in 36%. Myalgias and arthralgias were present in 26%. In 15% the initial symptom was jaundice without other symptoms. Most of the patients were admitted to the hospital a few days after the onset of their disease. When the disease was full-blown the main symptoms were abdominal distress (48%), asthenia (40%), and anorexia (40%). Fever was present in only 7%. The main physical sign was hepatomegaly with or without tenderness (68%). Splenomegaly was present in 13% and always associated with hepatomegaly. It was generally of a moderate degree and painless. Bilirubinemia was present in all but five patients who had the anicteric form of viral hepatitis. Blood cholesterol values were under 200 mg. per 100 cc. in 64% of the patients. Alkaline phosphatase levels exceeded 10 Bodansky units in only 13.4%. Of the flocculation tests the thymol turbidity was the most sensitive. In about half of the patients the strength of the flocculation tests decreased with the clinical subsidence of the disease and in the rest the tests remained positive up to six months after the clinical cure. In two patients they remained positive in spite of a negative liver biopsy. The main point of interest in the erythrocyte count was the presence of macrocytosis in 70% of the patients. The albumin-globulin ratio was inverted in 88%. Prothrombinemia was studied in only 99 patients, and in 49 it was below normal. It is difficult to say when hepatitis is cured, because no laboratory test gives this information and liver biopsy is not practical as a routine test.

Rabies Control.—Dr. Benjamin Blood, of the Pan-American Sanitary Bureau, as a result of a survey, stated that rabies is a problem in all Latin American countries except Uruguay. The Chilean government is cooperating with the bureau in its antirabies campaign. The vaccination of dogs must be supplemented by the capture of stray dogs. The absence of the sylvatic type of rabies in Chile makes the control of this disease much easier. The collaboration of the public is essential to the success of the campaign.

ENGLAND

Physique of School Children.—In a symposium in the *British Medical Journal* of June 25 it is stated that to obtain standards for somatotypy of children by physical anthopometry at the age of 11, measurements of 371 boys and 421 girls were made as an additional part of the routine medical examination in the city of Oxford schools during the period of January, 1953, to March, 1954. After discovery of significant relationships between physique and final honors among Oxford undergraduates, it was decided to compare the physique of the children with their marks in the entrance examination. The less muscular children are more often successful in passing the examination. The children's physiques were classified according to Sheldon and Tucker's somatotype method, with two important differences. First, since it was impossible to photograph the children, the estimates were based on physical measurements alone, whereas Sheldon uses mainly photoscopic methods. Second, since photographic standards for children have not yet been published, it seemed dangerous to adopt Sheldon's terminology; therefore, the components were renamed. The first component, endomorphy, was called fat (F); the second, mesomorphy, indicating bone and muscle development, was termed muscularity (M); and linearity (L) was substituted for the third component, ectomorphy. The ponderal index (height over the cube root of weight) was used as the basis for rating linearity.

The "11-plus" entrance examination consisted in 1953 of three papers—an intelligence test, an English test, and an arithmetic test—to which the Peel test of practical ability was added in 1954. Complete results were not available for the children who scored less than 70 in the intelligence test and for those absent from one or more of the written examinations. Although the former were automatically excluded by their low marks from taking any further examinations, their physique distribution is analyzed in the intelligence test section of the boys' part, since all of the very low scorers were boys. Results were analyzed in terms of those scoring above and below the mean for each subject. Of the girls' results, the most outstanding feature was that the less muscular sectors (in particular, LF) consistently, in all the tests, contained a greater proportion of girls scoring above the mean than the rest. The muscular-linear girls (LM and ML) varied in performance, while the muscular-fat ones (MF and FM) always had a lower percentage of high scores than the whole sample. The less muscular girls gained the largest number of grammar and technical school places, whereas the fat muscular girls received significantly few places. In all these tests stocky and tubby girls in sectors FM and MF did poorly as compared with the others. Many lean girls (LM) did well in the intelligence and English tests, but few did well in the arithmetic and practical ability tests. The slightly more muscular and less linear girls of sector ML, on the other hand, performed well at arithmetic and in practical ability, but did poorly in English and the intelligence tests. The boys' results were not as highly significant as were the girls'. There was, however, a consistent trend throughout all the results. The fattest boys (FM) were the most successful of the larger samples, and the muscular ones with secondary fat dominance were the least successful.

Experiments in Nursing.—There will be no reveille at dawn for the 64 patients who are to occupy two experimental wards at Larkfield Hospital, Greenock Royal Infirmary. Like patients elsewhere, those at Larkfield are normally called after 6 a. m. Hospital administrators have always said that the washing of patients must be completed by the night staff before they go off duty at about 8 a. m. In the experimental wards washing will be left to the day nurses who will be responsible also for bed-making. In return, nurses on night duty will take more part in the evening care of patients. In the new wards the main objective will be to provide more personal care by nursing patients in small groups. The wards are in a block, specially built to test new ideas in design and construction. A team of experts studying the problem included an architect, a physician, a nurse, a field-work organizer, a historian, and a statistician. They have been assisted by time-study engineers and others. A two-story building, the block has a 32-bed unit on each floor, one for men, the other for women. Each ward has centrally placed ancillary rooms, with 16 beds grouped on either side. This will cut the amount of walking done by average nurses while on duty between two and two and a half miles a day. Two experienced nurses will be in charge of the new wards. They will be given what clerical help they need so that they can devote maximum time to nursing care and teaching. They will control nursing teams of three, each with a trained nurse in charge and each caring for 16 patients. Each pair of teams will be helped by three relief nurses.

Maternal and Child Welfare.—The 42nd conference of the National Association for Maternal and Child Welfare was held at Church House, Westminster, in June. Sir Allen Daley said that at the time of the first conference in 1906, infant and maternal mortality were both five times greater than they are today. The Minister of Health said that for the first time in the history of this country the number of deaths from diphtheria was represented by a single digit (9), and the number of cases reported was 182. During the year the Minister of Health had tried to bring home to local authorities his concern at the bad effect on children's health, especially mental health, that followed the break-up of family life. It must be recognized that a team of people are involved in staving off these effects, and there can not be a thoroughly efficient service unless all parts of it work well and happily together.

Naval Hero.—Surgeon Lieut. C. E. Rhodes of the Royal Naval Volunteer Reserve lost his life on June 16 at the age of 27 in circumstances of great gallantry. He was serving on H. M. S. Maidstone, a submarine depot ship lying in Portland Harbor, when an explosion occurred in H. M. Submarine Sidon, which was alongside the Maidstone. He immediately boarded the submarine and without hesitation went below to help the injured. He succeeded in rescuing at least two of the crew, but when the order was given to abandon the sinking submarine, he did not return. Either he did not hear the order or he chose, true to his calling, to stay below tending the injured. The Sidon sank 20 minutes after the explosion. Dr. Rhodes had nearly completed his period of full-time national service. He was survived by a widow and a three-week-old daughter.

Joint Annual Meeting of British and Canadian Medical Associations.—The Joint Annual Meeting of the British Medical Association, the Canadian Medical Association, and the Ontario Medical Association, held in Toronto in June, attracted nearly 5,000 registrants. This is the fourth time that the British Medical Association has met in Canada. The last meeting in Toronto was in 1906. The new president, Dr. T. C. Routley, is not only president of the Canadian Medical Association but also of the British Medical Association. In his presidential address, Dr. Routley surveyed the medical and surgical scenes at the time of the three previous meetings of the two associations in Canada, the first being in 1897.

Chemotherapy of Bacterial Infections.—At the same meeting Professor Garrod of St. Bartholomew's Hospital, London, said that the various sulfonamides had similar antibacterial activities, whereas the antibiotics were much more selective in action, except that all the tetracyclines acted similarly. It is difficult for the clinician to keep up with all the new developments, particularly the new dosage forms. There are now 47 different dosage forms of penicillin. With regard to penicillin therapy it is better to have a persistent, even if low, blood level than a high, but short-lived, level. The indications for the use of antibiotics in different conditions can be divided into the absolute and the conditional. Use of penicillin is specific in scarlet fever, lobar pneumonia, gonorrhea, and syphilis; streptomycin is effective in tuberculosis and tularemia; chloramphenicol is effective in typhoid fever; and chloramphenicol and the tetracyclines are effective in typhus and other rickettsial infections. In the conditional group the particular strain or organism may not be sensitive, as with micrococci (staphylococci) in a hospital environment, or the condition may be due to a variety of organisms. The best course in such cases is to use the most likely antibiotic, pending a bacteriological investigation. Professor Garrod stressed the dangers of indiscriminate chemotherapy. The main abuses are the administration of agents to undiagnosed patients, to patients with nonsusceptible infections, to patients with trivial complaints such as colds, and to patients for prophylactic use. Chemoprophylaxis is, however, justifiable in major operations on the chest, abdomen, and brain, in complicated labor, and for prophylaxis in patients with rheumatic fever, but about 90% of the antibiotics prescribed are not justified. In a census of surgical patients more antibiotics were being given for prophylaxis than for treatment. Apart from the waste of money if improperly used, the antibiotics have dangerous side-effects in a small number of patients. These side-effects include allergic responses, aplastic anemia, and fulminating, resistant micrococcic enteritis. Chemoprophylaxis is not needed in aseptic operations, normal labor, or ordinary dental work. It is regrettable that in Britain the hospital doctor is tempted to use chemoprophylaxis as a protection against litigation should any untoward incident occur.

Dr. T. E. Ray of Toronto said that bacterial resistance to antibiotics varied with the locality and with the frequency of use of particular antibiotics. Inadequate dosage is also a cause of the emergence of resistant strains. This would not matter if the organisms became confined to one patient, but they become disseminated and infect other patients. In the Hospital for Sick Children, Toronto, nearly two-thirds of the pathogenic streptococci isolated in 1954 were penicillin-resistant, and one-third was resistant to streptomycin and the tetracyclines. The incidence of resistance to chloramphenicol and erythromycin was still low. Escherichia coli showed increasing resistance to streptomycin and the tetracyclines; Proteus and Pseudomonas aeruginosa were only occasionally sensitive, but many important pathogens were still fairly sensitive. These included the beta-hemolytic streptococci, the Diplococcus pneumoniae, the Neisseria meningitidis, the Neisseria gonorrhoeae, type B Hemophilus influenzae, and Treponema pallidum. The change is particularly evident in hospitals, but not so much in private practice, although resistant strains are appearing in the home. As the use of antibiotics becomes stabilized, the incidence of resistant strains in the hospitals does likewise. Treatment with antibiotics allows resistant mutant cells to survive treatment and fails to suppress any naturally resistant strains that may be present. Dissemination of these occurs via healthy or convalescent carriers. The problem may be solved by avoiding indiscriminate and prolonged use of antibiotics or by using them in rotation and isolating patients infected with highly resistant strains.

Dr. K. J. R. Wightman of Toronto said that in choosing an antibiotic the patient should be carefully examined before a decision is made as to whether one is needed and that if one is needed a careful choice should be made of the antibiotic. The severity of the infection, the accessibility and type of the lesion, the resistance mechanisms, both general and local, the previous reactions to antibiotics, and the bacteriological diagnosis influence the use and choice of antibiotics. The patient must have some natural resistance to the infection as well. Preference should be given to such bactericidal drugs as penicillin, streptomycin, and polymyxin. Absence of side-effects is also important, and the patient should be questioned on any previous reactions to antibiotics. Close cooperation between clinician and bacteriologist is necessary for rational and effective chemotherapy. Before deciding to use a particular drug, the sensitivity of the organism, absorption, diffusibility, mode of action, risk of toxic effects, ease and flexibility of administration, and even cost to the patient should all be considered. Antibiotics can be divided into three broad groups according to their bacterial spectrum. In the first group is penicillin, particularly active against gram-positive bacteria. Erythromycin is an alternative drug, useful particularly *in penicillin-resistant micrococcic infections.* Bacitracin should only be used in severe infections because of its nephrotoxic effect; it is useful for topical application because of the low risk of sensitization. The second group includes streptomycin and dihydrostreptomycin, which are of limited use because of the early development of drug resistance and the risk of eighth nerve damage. Neomycin has a nephrotoxic effect and is only suitable for local use. Polymyxin is particularly effective against the Pseudomonas organisms. In the third group are the broad spectrum antibiotics. They are bacteriostatic, apt to produce gastrointestinal upsets, and dangerous because of the risk of superinfection in the alimentary tract with micrococci, coliform organisms, and yeasts. These complications are less likely with chloramphenicol.

Prof. J. W. Crofton of Edinburgh summarized the recent work done in Britain by the Medical Research Council groups with streptomycin and isoniazid. With effective chemotherapy tubercle bacilli can be eliminated from the sputum in 6 months without the emergence of drug resistance, and most patients can get back to work in 12 to 18 months, although in some such patients chemotherapy may have to be continued. Effective chemotherapy includes such combinations as 1 gm. of streptomycin daily, with 100 mg. of isoniazid twice daily, or 1 gm. of streptomycin daily, with 5 gm. of *p*-aminosalicylic acid four times daily, for patients under 30 years of age. For older patients an alternative scheme is 1 gm. of streptomycin twice weekly, with 100 mg. of isoniazid twice daily and 5 gm. of *p*-aminosalicylic acid twice or four times daily. Treatment with streptomycin, twice weekly with isoniazid and *p*-aminosalicylic acid in full daily doses is not without risk, as drug resistance may develop in some patients. In cases of drug resistance the drug to which the organism is still sensitive can be used with viomycin, oxytetracycline, or pyrazinamide. Chemotherapy should usually be continued for 9 to 12 months and, if cavities are present, for 9 to 12 months after the last positive sputum, or until the cavity appears to be closed. If chemotherapy is effective deaths are rare, unless treatment is delayed or postoperative death results. Of 107 patients treated over a period of three years, only two deaths occurred, although 31 of these patients had advanced disease. All the others became sputum negative, and 97% were able to perform some work.

Anesthesia.—At the same meeting Prof. Robert Macintosh of Oxford made a plea for simplicity in anesthesia. He thought that in many instances the anesthetic apparatus was unnecessarily complex, especially outside the larger hospitals, and he doubted whether the development of apparatus along "battleship" lines indicated progress. Nitrous oxide and cyclopropane although useful are not indispensable, and anesthesia can be carried out in an emergency without gas cylinders. Operations can now be performed with the patient under light general anesthesia to produce unconsciousness and with a muscle relaxant to abolish reflex responses. The latter are safe in competent hands provided a needle is strapped into a vein for intermittent injections. The one most useful piece of apparatus is a small bellows, with unidirectional valves in the supporting base to assist respiration. An oxygen cylinder is not necessary for such equipment; air, in fact, is safer, because oxygen might mask deficient pulmonary exchange. If an inhalation agent were needed, it could be run in through a tap at the base of the bellows, or a vaporizer could be attached for ether or trichloroethylene. For most operations air is adequate for oxygenation, and it is only in intrathoracic surgery that supplementary oxygen is needed, because in this procedure the lungs are seldom fully inflated. Sir Robert corrected two common errors: (1) that controlled respiration can be carried out by positive pressure without an endotracheal tube and (2) that closed-circuit anesthesia is not essential for the maintenance of controlled respiration.

Dr. C. Langton Hewer of St. Bartholomew's Hospital, London, deprecated the use of the Trendelenburg position in surgical operations because there is no need for it with the use of muscle relaxants. Its only value is in the treatment of shock. During operations the position compresses the lungs and reduces vital capacity; produces hypoxia and hypercapnia; tends to drown the patient with gastric juice, saliva, and mucus that collect in the nasopharynx; raises the blood pressure; and causes thrombosis in the legs and pulmonary embolism. The use of shoulder rests may also cause a palsy of the brachial plexus.

Dr. H. R. Griffiths of Montreal said that anesthetists should be trained as clinicians not as scientists but that scientists should advance the frontiers of anesthesia. He visualized the increased use of gases because they were more controllable in use and more readily eliminated than barbiturates, which he felt should only be used to induce sleep. Dr. Griffiths, who was the first to use curare in anesthesia, said that the safest and best muscle relaxant was succinylcholine, because it was so rapidly hydrolyzed. There is no future in hypothermia in anesthetic practice unless better drugs are discovered. For the moment it should be reserved for cardiac operations. The anesthetist of the future must be a physician, a pharmacologist, a physiologist, a toxicologist, a biochemist, and an electronic engineer.

Dr. L. Longtin of Montreal described a new technique of intubation for the prevention of contralateral infection during pulmonary operations. Two separate cuffed tubes connected to the same anesthetic machine deliver anesthetic gases to the lung. One is placed in the left bronchus to deliver gas to the left lung, and, by blowing up the cuff, the latter can be sealed off. The other is placed in the trachea, 2 cm. below the vocal cords, and delivers gas to the right lung only, as the left side becomes sealed off. Relaxation is secured with succinylcholine

Discussing the techniques used for anesthetizing newborn infants, Dr. Cope of University College Hospital, London, said that he pushed muscle relaxants to the stage of complete curarization, using *d*-tubocurarine chloride in a dose of 0.3 mg. per kilogram of body weight. Oral intubation is performed with use of succinylcholine, and artificial ventilation is carried out, first with oxygen and then with a mixture of oxygen and nitrous oxide in equal volumes. Meperidine is sometimes used in a dose of 0.5 mg. per pound of body weight to produce sensory depression. As it is fatally easy to overhydrate babies with fluids used intravenously, these should be limited to 10 ml. in 24 hours.

Dr. Bromage of Chichester, England, described a new technique for assessing analgesic drugs. He said that the vital capacity was reduced by 60 to 80% during the 48 hours after upper abdominal operations, because of pain on inspiration, and that it was measurable by spirometry. Hence, the potency of an analgesic agent could be expressed by the degree to which it restored the vital capacity.

The use of chlorpromazine in anesthesia was commented on by Dr. D. A. Hopkin of London, who said that he had used it in 2,000 operations as an adjuvant to anesthesia. It exerts a selective depression on the subcortical centers and prepares the patient halfway for surgical anesthesia. Recovery can be prolonged with this drug as it intensifies the action of anesthetic agents and reduces muscle tone. Dr. Hopkin was impressed by the absence of operative shock when chlorpromazine was used. In fact, the signs of shock can be reversed in a patient with a perforated viscus, so that he is already prepared for operation. The speaker was also impressed by the good postoperative condition of patients who had been given chlorpromazine. Pulmonary complications are reduced, there is less vomiting and coughing, and patients are less restless and more cooperative. There is no convincing evidence that hypothermia is essential for chlorpromazine to exert its action. Many of its effects can be explained by its depressive action on what is known as the reticular activating system of the brain stem.

Simple Obesity.—At the same meeting Dr. E. R. Cullinan discussed the essential nature, effects, and treatment of simple obesity. Average weight-for-age tables of the life insurance companies are not satisfactory, and the Metropolitan Life Insurance Company has prepared tables with no distinction for age after 25 years, giving a range for three groups of differing build—slight, medium, and heavy. Simple obesity is the result of an excess of caloric intake over output. Constitution and inheritance may play a part. There is no abnormal metabolic pathway in the obese. Appetite is controlled by the hypothalamus. Psychic influences can affect the hypothalamic control. Weight reduction is best achieved by a high-fat, low-calory diet, although, in practice, restricting carbohydrates is usually sufficient. Exercise should be increased, but this should not be violent as it increases appetite. The amphetamine drugs have some value in the treatment of obesity.

Delay in Treating Cancer.—At the same meeting Dr. Ralston Paterson of Manchester asked whether the early treatment of cancer was of proved value. The term "early" is often equated to the time interval from the first symptom, but this disregards the different rates of growth found in different tumors. Patients with growths of a limited extent, whatever the duration of symptoms, have a much better chance of being cured, although cure can never be guaranteed to anyone regardless of how early treatment is begun. Patients delay getting advice because of ignorance and fear. Ignorance is the cause of delay in cancers of the cervix, mouth, and skin, and fear is the *main* cause of delay in breast cancer. Fear causes more delay than ignorance because the layman still believes that cancer is incurable. In an investigation carried out at Manchester only one-third of the women questioned thought that cancer was curable. In a similar investigation in the United States, two-thirds of the women thought it was sometimes curable. Any public education scheme must dispel the fear of cancer and emphasize the fact that some cancers are curable.

War Pensions.—The "Report on War Pensioners," published by the Ministry of Pensions and National Insurance, shows that at the end of 1954 the number of disability pensions being paid to veterans of World War II was just over 367,000, compared with 375,528 a year earlier, and the number of such pensions being paid to veterans of World War I was 273,335, compared with 284,484 at the end of 1953. Treatment allowances were granted to 43,750 pensioners prevented from working because they were receiving approved treatment for service-connected disability. During the year, 93,000 such pensioners of World War II were examined by medical boards, and 70% retained their current pensions unaltered. A total of 4,087 pensions were awarded up to the end of 1954 for service in Korea (2,055), Malaya (1,162), Suez Canal Zone (819), and Kenya (51).

NEW ZEALAND

Antileptospiral Effect of Milk.—An epidemic of leptospirosis has occurred in New Zealand. Of the 262 patients involved, 200 were dairy farmers and their families, and the others were persons connected with the handling of livestock (freezing workers, transport workers, and veterinary surgeons). The absence of milk-borne epidemics in New Zealand and in the large number of countries where there is bovine leptospirosis made it desirable to initiate an investigation. Kirschner and his co-workers (*Proc. Univ. Otago M. School* 33:4, 1955) showed that human, cow, and goat milk and human colostrum have a strong lytic action on Leptospira. There was no difference in the results obtained with the three types of Leptospira prevalent in New Zealand. The results have been confirmed by repeating the experiment with a virulent strain of Leptispira icterohaemorrhagiae, the destruction of the organism being shown by injection into guinea pigs. Certain physicochemical properties of the lytic agent suggested that it might be lysozym, but this possibility appears to be unlikely because egg white, saliva, or tears, known sources of lysozym, do not affect Leptospira. The factor also differs from lactenin, a substance in milk that kills streptococci, since it is not destroyed by glutathione, which destroys lactenin.

NORWAY

Sanitation of Summer Camps.—The Hygiene Institute of the University of Oslo has sent a memorandum to the Minister of Health urging him to centralize the measures necessary for keeping summer camps sanitary. Since 1940 the tourist traffic in Norway in the summer has risen by 250% whereas hotel accommodation has risen by only 15%. At the same time more and more tourists are avoiding the hotels and availing themselves of the overnight hospitality afforded by summer camps. About 35% of the Swedish visitors to Norway in July and August, 1954, were camping tourists. At one time the Norwegian Royal Automobile Club took a hand with the organization of summer camps, but some of this work has now been taken over by the Norwegian Automobile Association. In the summer of 1954, 4,400 tourists from abroad were questioned on leaving Norway about their experiences in the summer camps they had visited. Their comments were not flattering. In *Tidsskrift for den norske lægeforening* for May 15 Dr. Kaare Svendsen gives an account of his inspection of four summer camps run by landowners as private undertakings. The local sheriff has insisted that watchmen be employed and that a record be kept of all who stay a night or more. The local health authorities have framed rules for the sanitary control of these camps, and their owners are requested to provide sanitary drinking water, refuse disposal, and privies. Svendsen points out that although the camps he visited were among the best of their kind in Norway, they presented health risks to both the tourist and the local population. He recommends that the sanitary control of summer camps should not be left to the initiative of the local health authorities, whose activities vary from one district to another, but that a uniform system of control be directed by the Ministry of Health.

TURKEY

Pneumoperitoneum in Pulmonary Tuberculosis.—In *Tüberküloz* (vol. 9, no. 4) Dr. Tevfik Gökce and his co-workers report that in 1937 pneumoperitoneum was used in six of their patients but was then discontinued until 1949. Since then it was administered 1,760 times. Of the 1,000 patients who were followed up, 10 had moderate, 60 had marked, and 161 had progressive lesions in one lung; and 12 patients had moderate, 179 had marked, and 578 had progressive lesions in both lungs. The diaphragm ascended on the average of 4.5 cm. and most often on the right side. Pneumoperitoneum was performed in 28 patients simultaneously with phrenic écrasement, in 62 patients simultaneously with artificial pneumothorax, and in 104 patients after pneumothorax proved ineffective. In 34 patients pneumoperitoneum was performed with thoracoplasty and pneumothorax as a control for the lesions of the other side. In 120 patients the initial pneumoperitoneum was performed to stop hemorrhage. During the therapy 762 patients gained weight, 96 showed no change, and 142 lost weight. In 686 patients the sedimentation rate decreased; in 275 there was no change; and in 39 an increase in the sedimentation rate was observed. In 350 patients there was an increase in vital capacity; in 230 there was no change; and in 420 there was a decrease in vital capacity. It was observed that after pneumoperitoneum the vital capacity decreased from 5 to 10% but reverted to normal after the lesions and empyema disappeared. Pneumoperitoneum had beneficial effects on 120 patients with hemorrhage. Clinical, radiological, and laboratory examinations revealed the following effects of pneumoperitoneum on patients with lesions and cavities: 14% recovered; 58% were improved; in 26% the therapy was ineffective; and in 2% the condition was aggravated. During the first week of the therapy loss of appetite and loss of weight was observed in almost all patients, and brief, moderate, peritoneal reactions were observed in 5%. In 5 of the 18 patients in whom an inguinal hernia developed, an operation was performed and in 4 of these pneumoperitoneum was continued after the operation. In 19 of the 23 patients in whom an umbilical hernia developed, pneumoperitoneum was discontinued. When such a hernia can be controlled with bandaging, however, there is no contraindication to pneumoperitoneum. Ascites developed in 5% of the patients, but absorption occurred spontaneously. A few subcutaneous emphysemas were traced to faulty technique. Air embolus occurred in two patients, both of whom recovered. Mediastinal emphysema developed in one patient; he recovered. Acute appendicitis necessitating appendectomy developed in three patients. Cavitary souffles were observed in 1.5% of the patients. Lobar atelectasis was observed in two patients. Torsion of the omentum, obliterative tuberculous or hemorrhagic peritonitis, or tuberculous meningitis was not observed. The authors concluded that, as with artificial pneumothorax, pneumoperitoneum should be continued for three years.

MEDICAL LITERATURE ABSTRACTS

NEUROLOGY & PSYCHIATRY

Contribution to Therapy and Etiology of Multiple Sclerosis. H. Tschabitscher, T. Wanko, H. Schinko and B. Fust. Schweiz. med. Wchnschr. **85**:556-557 (June 4) 1955 (In German) [Basel, Switzerland].

Of 85 patients with multiple sclerosis of several months' to 34 years' duration, 50 were treated with isoniazid, 21 were treated with iproniazid, and 14 were subjected to a double-blind test with isoniazid and placebos. Isoniazid was given in daily doses of 500 mg., 400 mg. of which was given in four divided doses of 100 mg. orally and 100 mg. intravenously. The average duration of the treatment was 37 days, and the average total dose of the drug was 21 gm. Of the 50 patients treated with this drug, 28 had a chronic course, i. e., their disease did not show any tendency to improvement for at least three years before isoniazid therapy was instituted; in the other 22 patients the course of the disease was characterized by recurrent bouts. Of these 50 patients, 24 were improved in that the neurological symptoms were markedly alleviated, 17 were improved without substantial reduction of the neuropathological signs, 7 remained unchanged, and 2 became worse. Undesirable side-effects in the form of a transient urticarial rash occurred in two patients. Follow-up examination, three to six months after treatment was terminated, showed that the favorable effect of isoniazid continued in most of the patients with the chronic course, but in only one-third of those with recurrent bouts. Iproniazid was given in daily doses of 300 mg., 250 mg. of which was given in five divided doses of 50 mg. orally and an additional 50 mg. intravenously. The average duration of the treatment was 37 days and the average total dose 14 gm. Of the 21 patients treated with this drug, 12 obtained marked improvement, 3 were improved, 5 were unchanged, and one became worse. Several patients complained of dryness of the mouth, which as a rule subsided after four days. Three patients had mild edema in the lower extremities, but it disappeared spontaneously. Of the 14 patients who were subjected to a double-blind test, 8 were given isoniazid according to the same schedule as the 50 patients and 6 were given placebos. Of the eight patients who were given isoniazid, four were markedly improved, two were improved, and two remained unchanged. Of the six patients who were given placebos, one was improved, three were unchanged, and two became worse. The results obtained with the antituberculous drugs in the authors' patients with multiple sclerosis were superior to those obtained with any other treatment for multiple sclerosis. The cerebrospinal fluid of 30 patients was examined and found to contain Mycobacteria, the identity and significance of which are at present being investigated.

Tic Douloureux and Facial Pain: Therapeutic and Pathogenetic Considerations. E. Sperling and A. Stender. Deutsche Ztschr. Nervenh. **173**:161-183 (No. 2) 1955 (In German) [Berlin, Germany].

The authors review observations on 524 patients with pains in the region of the trigeminal nerve. They found that in typical tic douloureux the operation of Frazier or gangliolysis will generally produce complete freedom from pain. After gangliolysis no impairment of the sensory perception remains. This method represents a superior surgical method, provided i favorable results are permanent. Neuralgias in the first bran of the trigeminal nerve must be carefully analyzed with rega to the character of the pain. Operations on the gasserian ganglio are indicated if the pain occurs in the form of true paroxysm In most patients, however, the pain in the region of the for head and eye is of a different character, that is, it is a burni pain. It may appear alone or in the form of an atypical involv ment in an otherwise typical tic douloureux in the second a third branches. In such patients, operations on the gasseri ganglion may be followed by residual anesthesia doloros Blockage of the gasserian ganglion by means of alcohol shou be rejected in patients with atypical pain in the first branc In the presence of neuralgias of the first branch, operations the posterior cranial fossa (Dandy, Sjöquist) produce mc favorable results than do operations on the gasserian ganglio In the typical forms of tic douloureux, hydantoin preparatio such as diphenyl hydantoin, should always be tried first, becau these preparations usually produce immediate improvement a bridge the period until there is spontaneous recovery or ur an operation can be performed. Diffuse atypical pains in t region of the trigeminal nerve contraindicate operations on t gasserian ganglion. In these patients the pain is caused by t sympathetic nerves, and the tracts that conduct this pain cann be reached by operations on the somatic nervous system. In m patients these diffuse atypical pains extended to the occiput a the neck. The application of ultrasonic therapy to the cervi spine was found to be effective in many of these patients, p vided no contraindications existed to this treatment. In the sev forms of sympathetic facial pains, such as in anesthesia doloro artificial hibernation has proved helpful. The authors believe t vasomotor disturbances, possibly of the gasserian ganglion, n explain the pathogenesis of true trigeminal neuralgia.

Serpasil as Sedative in Psychiatry. K. H. Fremming and I. F regaard. Ugesk. læger **117**:599-603 (May 12) 1955 (In Dani [Copenhagen, Denmark].

The sedative effect of Serpasil was tested in a heteroge group of 98 patients with the common characteristics of psyc motor unrest, restlessness, tension, and aggressiveness; 83 w schizophrenics. No difference was seen on parenteral and peroral administration. To avoid the suggestive effect of a r remedy 37 patients were given Serpasil in periods alternat with placebos. The Serpasil dosage applied in most cases is tween 2 and 4 mg. daily or, for old patients, between 0.5 a 1.5 mg. daily. In 61 cases the effect was good or tolerably go in 37, doubtful or absent. In all cases the treatment was f lowed by fall in blood pressure, bradycardia, and lowered bo temperature. When the systolic blood pressure fell below mm. Hg Serpasil dosage was reduced or temporarily suspend as also when the pulse rate was less than 46 per minute. Serpa was substituted for electroshock treatment in 33 schizophre patients who had received regular electroshock treatment f a shorter or longer period of years. Patients with recent mani responded poorly, but the results were often good in patie with chronic schizophrenic psychoses. The best results were distressed patients with moderate agitation. Caution is urged the treatment of elderly patients and of patients with cardi disease. There were no dangerous side-effects during the Serpa treatment. In five cases there was stuffy nose and in six cas a Parkinson-like syndrome.

The Effect of Chlorpromazine ("Largactil") on Glucose Tole ance. F. B. E. Charatan and N. G. Bartlett. J. Ment. Sc. 10 351-353 (April) 1955 [London, England].

The use of chlorpromazine is now firmly established in ps chiatry. A hyperglycemic effect in man has been reported a might be of importance if, for example, in schizophrenia, chlo promazine were combined with insulin coma treatment. An i vestigation was carried out to study the effect of chlorpromazin

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

on glucose tolerance in 11 schizophrenic patients about to be treated with chlorpromazine. The patients were taking the ordinary hospital diet. A control glucose tolerance curve was carried out in the fasting recumbent subject after the ingestion of 50 gm. of glucose in a single dose. The fasting blood sugar, and the blood sugar at one-half, one, one and one-half, two, and two and one-half hours after the ingestion of glucose was estimated by the method of Folin and Wu on capillary blood. The test was repeated two or three days later with 50 mg. of chlorpromazine in 20 ml. of isotonic sodium chloride solution given intravenously immediately after the ingestion of glucose by the patient. It was found that the intravenous administration of chlorpromazine produced a significant delay in the expected fall in the blood sugar level after the ingestion of 50 gm. of glucose by mouth. This effect is considered to be due to a depressant effect of chlorpromazine on liver function or to increased secretion of glucocorticoids from stimulation of the adrenal cortex.

Is the Diagnostic Study of the Cerebrospinal Fluid Approaching a Crisis? V. Kafka. Deutsche Ztschr. Nervenh. 173:103-110 (No. 2) 1955 (In German) [Berlin, Germany].

Some investigators have advanced the idea that since all proteins in the cerebrospinal fluid originate from the blood, the examination of the cerebrospinal fluid is only a test of the permeability of the meninges. Other arguments were added to question the validity of the diagnostic examination of the cerebrospinal fluid, but the author shows that rather than approaching a crisis, the study of the cerebrospinal fluid has been advanced, particularly by electrophoretic studies. He shows that, contrary to the opinions of some, electrophoresis cannot replace either chemical fractionation of the proteins of the cerebrospinal fluid nor the colloidal tests, and he urges that in the future all three of these methods should be used. This will not only bring closer the solution of the cardinal question as to where the proteins originate and what their function is but will find new diagnostic pictures. More detailed analysis, rather than the cursory methods now prevailing, will have to be used, however, to obtain more information about diagnostic problems and about the physiological and pathological aspects of the central nervous system.

Idiopathic Paralysis of the Diaphragm. G. Wense. Wien. klin. Wchnschr. 67:417-418 (June 10) 1955 (In German) [Vienna, Austria].

An attempt was made to determine the cause of idiopathic unilateral paralysis of the diaphragm of three to four years' duration in 14 men between the ages of 47 and 71 years. Eight patients had paralysis on the left side and six on the right side. Some indications for the cause of the paralysis were observed in eight patients. One had a moderate-sized goiter extending substernally on the paralyzed side, one had been operated on for a similar type of goiter, one had a definite diaphragmatic pleuritis with a slight pleural effusion, one had a bronchial carcinoma at a considerable distance from the phrenic nerve, but microscopic examination revealed that the nerve was surrounded by chronic inflammatory infiltration and there was edematous swelling. The history of four patients revealed that they had had pneumonia on the paralyzed side and fibrous changes and thickened pleura were present as remainders of the previous inflammatory process. It is possible that in these four patients the phrenic nerve had become imbedded in the fibrous tissue and had lost its function. In the remaining six patients no indications for the cause of the paralysis of the phrenic nerve were found.

PEDIATRICS

Infantile Spastic Hemiplegia. M. A. Perlstein and P. N. Hood. Am. J. Phys. Med. 34:391-407 (June) 1955 [Baltimore].

This report is concerned with a study of 334 patients with infantile spastic hemiplegia observed by the senior author during the past 10 years. Approximately 30% were private patients; 25% were seen at the Children's Neurology Clinic of the Cook County Hospital, Chicago; and the remaining 45% were from itinerant clinics throughout the midwest. Hemiplegia of the right side predominated over that of the left side in a ratio of 5:4. The right-sided and left-sided hemiplegias were distributed randomly between the congenital and postnatally acquired, those in males and females, and those with or without seizures. There was no significant difference in the intelligence or in the age of acquiring speech; the only other significant difference between those with involvement of the right side and those of the left was the even greater proportion of right-sided hemiplegia (2:1) in the congenital cases with birth weights of 8 lb. 3,628.7 gm.) and above. Spastic hemiplegia occurred more often in males than in females (4:3); however, sex was not related to other variables in this series, including birth weight. Negroes did not differ from whites, with the exception of their greater representation in the postnatally acquired and in the seizure groups. These differences were thought to be the result of socioeconomic factors rather than racial factors. Postnatally acquired forms accounted for about a third of the present series. The time of onset of hemiplegia showed no relationship to race, sex, side of involvement, or intelligence; however, an earlier age of walking and talking was noted in the patients in whom onset of cerebral palsy predated the acquisition of these skills, as compared with those with congenital hemiplegia. The incidence of seizures in this series was higher than that reported for all types of brain injury for mixed spastic groups and for most other series of spastic hemiplegia. Seizures were significantly more prevalent in those with the acquired forms and in the mentally defective patients; moreover, patients with seizures showed a significantly lower mean I. Q. score. Seizures were also associated with delayed onset of walking and talking but were not related to birth weight. Patients with spastic hemiplegia were approximately 20 I. Q. points retarded in comparison with normal children. Although the mean I. Q. scores did not differ significantly, there was a significantly greater number of mental defectives below than above the age of 6. The mentally defective group walked and talked later than did the educable group. Those of I. Q. between 90 and 110 percentile differed only slightly from normal children in walking and talking. Infants with spastic hemiplegia were 0.7 lb. (317.5 gm.) lighter than normal infants, the mean birth weight being 6.4 lb. (2,903 gm.). The proportion of premature infants and abnormally heavy birth weights was significantly greater in infants with spastic hemiplegia than in normal infants. There was a relationship between the age of walking and the age of the onset of the spastic hemiplegia in the acquired cases; other variables were not related to the age of onset in acquired hemiplegia.

Congenital Pneumonia: A Clinical Summary. A. J. Schaffer, M. Markowitz and A. Perlman. Maryland M. J. 4:327-333 (June) 1955 [Baltimore].

Congenital pneumonia may be acquired days or weeks before delivery or it may have its inception during some stage of labor. Autopsies were performed on 76 infants at the Maryland Women's Hospital. These were either stillborn infants or those who died within the first three days of life. Pulmonary inflammation was found in 27 (35%); in 7 it was considered to have constituted a contributory cause of death; in 6 others it was the sole discoverable cause of death. The following conclusions were drawn from a careful study of the 13 severe cases in the Women's Hospital plus 15 comparable cases from the Johns Hopkins Hospital. Ten examples were culled from the 28 for this study of clinical characteristics. The rest were eliminated because they were stillborn births or because other lesions were found at autopsy that might have confused the symptomatic picture. Six of the 10 were full-term infants, and 4 were premature. All the full-term infants were sick at birth. Three showed characteristic asphyxia livida, two had asphyxia pallida, and the sixth breathed promptly but was grayish and dusky in color. Breathing time in the others was delayed 2.5 to 10 minutes; crying was delayed or never occurred. The respiration was abnormal after spontaneous breathing was established. Physical signs varied. In most, dulness to percussion could be elicited and either rhonchi or fine crackling rales could be heard. Fever occurred in all the mature infants. Neurological complications were present in four of the six. These consisted either of persistence of flaccidity or of the development of hypertonicity and rigidity of all extremities and back. The heart failed in two, as evidenced by cardiac enlargement, poor heart sounds, and enlargement of the liver. In the premature infants who died of pneumonia, the clinical picture was much less sharply defined. They were all tiny (1 to 2½ lb. [453.59 to 1,134 gm.]), and they all became deeply cyanotic shortly after birth. Roentgenoscopy shows a fairly characteristic distribution of shadows. Intrauterine pneumonia must be differentiated from a number of morbid conditions that commonly affect the newborn infant. This task is rendered doubly difficult by the fact, demonstrable by postmortem examination, that pneumonia often complicates many of these same conditions. The authors briefly discuss the differentiation of hyaline membrane disease, atelectasis, and pneumothorax. Congenital pneumonia is not necessarily fatal. Vigorous antibiotic therapy of mothers whose membranes had ruptured prematurely will probably, although not surely, prevent a certain number of cases. Antibiotic therapy of the infant must be begun at the first suspicion that pneumonia might be present, and must be intensive. Both the pediatrician and the obstetrician must develop a greater awareness of this condition.

Anemia in Premature Infants. R. Clément. Presse méd. **63:**935 (June 18) 1955 (In French) [Paris, France].

The cause of the anemia seen in premature babies is a marked deficiency in hematopoietic activity during the neonatal period. Premature infants begin life with a greater volume of blood than babies born at term: 108 ml. per kilogram, dropping to 73 ml. per kilogram toward the seventh week of life. The volume of red blood cells falls from an estimated 46 ml. per kilogram at birth to 16 ml. by the seventh week. The number of reticulocytes falls extremely low during the first week of life and remains so for the next five to six weeks. During this period, the fall in red blood cells and hemoglobin level is considerable: 1.1 to 1.3% daily in the case of the former and 1.2 to 1.43% daily in the case of the latter. Spontaneous improvement, heralded by reticulocytosis, begins after the five-to-seven-week period. During the first three or four months of life the body of a premature infant has more iron than is necessary for hemoglobin synthesis, so iron therapy is not indicated at that time. It is of value later on. Transfusion therapy has proved its merit in the treatment of anemia of prematurity, but it should be discontinued after hematopoiesis picks up, because it might interfere with the process of spontaneous correction.

Variations in Secondary Antibody Response to Specific Antigens. M. Siegel. J. Pediat. **46:**631-641 (June) 1955 [St. Louis].

The data described were obtained among patients in an institution for the feeble-minded. Since the patients remained at the institution for many years, it was possible to observe them for prolonged periods and to employ as controls uninoculated individuals living under the same environmental conditions. Three types of antibody response to reinoculation were observed, depending on the antigen used. An accelerated and very marked increase in circulating antibodies commonly associated with a booster dose was seen after the use of tetanus toxoid and is characteristic of the response to bacterial toxins or toxoids. An accelerated but somewhat less marked secondary reaction was observed after the use of typhoid vaccine and is said to be typical of antibody formation following particulate antigens like bacteria, Rickettsia organisms, and viruses. In the case of pneumococcic polysaccharides, no increase in antibodies could be detected after reinoculation until many years after the primary stimulus, when the circulating antibody content was very low or nonexistent. The degree and duration of the secondary reaction also varied with the host. Individual differences were detectable with each antigen used. The individual's secondary reaction pattern to a specific antigen appeared to be reproducible by the use of a single dose only; however, there seemed to be little relationship between his responsiveness to the different types of antigen, that is, to tetanus toxoid and typhoid vaccine. The antibody content in the blood stream was lower among individuals with mongoloid features. The relation of these results to hormonal deficiencies reported in the mongoloid is conjectural at present. Electrophoretic analysis of pooled serum revealed comparable levels of gamma globulin in the mongoloid and normal individuals tested. The foregoing differences in response to reinoculation are not only of scientific interest but also of practical importance in the prevention o modification of clinical infection by means of active immunization. They suggest that different cellular processes might b involved in the formation of various types of antibodies.

Measles Encephalitis: I. Prophylactic Effect of Gamma Globu lin. M. Greenberg, O. Pellitteri and D. T. Eisenstein. J. Pediat **46:**642-647 (June) 1955 [St. Louis].

The authors tried to determine whether gamma globulin i of value in preventing the encephalitic complications of measles One hundred sixty-five cases of measles encephalitis reporte in New York City from the beginning of 1949 to July 1, 1954 were investigated epidemiologically. This number occurre among a total of 115,847 cases of measles, that is, there wa one case of encephalitis for each 702 cases of measles. It wa somewhat higher in females (1:611) than in males (1:817). Th incidence of the complication increased with the increase in ag of the patients with measles. It was one and one-half times a high in children 5 to 9 years of age and three times as high i those 10 to 14 years of age as in those under 5 years of age The case fatality rate was 15%. It was twice as high in female as in males and twice as high in children under 5 years of ag as in those 5 to 9 years of age. There were no deaths in olde children. Sequelae occurred in about 9% of the cases, divide equally between boys and girls. They occurred about six time more often in those 5 to 14 years of age than in those unde 5 years. There were none in children 15 years of age or olde All but one of the cases of encephalitis occurred in childre who had not received prophylactic doses of gamma globuli prior to onset of measles, although there were distributed du ing the period of the study about 300,000 doses of gamm globulin for children under 5 years of age and, during the fir four years of the study, about 85,000 doses for those 5 yea of age or older. The authors feel that encephalitis is a ra complication of measles modified by gamma globulin.

Measles Encephalitis: II. Treatment with Gamma Globuli M. Greenberg, E. A. Appelbaum, O. Pellitteri and D. T. Eise stein. J. Pediat. **46:**648-653 (June) 1955 [St. Louis].

Theoretically, it is improbable that a specific antiserum w be effective in treatment unless given early in the course of t disease, when the causative organism or its toxin is still circul ing in the blood. Once the virus has become attached to t cell it cannot be neutralized by antibody. In measles, the medi day of onset of the complicating encephalitis occurs about days after the beginning of the rash. By then the upper respi tory discharges contain no virus and the antibody titer of t serum is fairly high. It is difficult to see how the use of gamm globulin could affect the course of the complications or det mine their outcome. Of 159 patients with measles encephali under the age of 15 years, 51 were treated with gamma glob lin and 108 were not. About 25% of the children died or d veloped permanent sequelae, and the percentage was the sa in the two groups. No significant differences in results betwee the treated and the untreated were found when compariso were made by age groups or by amount of treatment or b severity. The authors conclude that gamma globulin has n value in the treatment of measles encephalitis.

Study of Illness in a Group of Cleveland Families: VIII. Rela tion of Tonsillectomy to Incidence of Common Respirator Diseases in Children. L. P. McCorkle, R. G. Hodges, G. F Badger and others. New England J. Med. **252:**1066-1069 (Jun 23) 1955 [Boston].

The question of whether an excessively large number of com mon respiratory infections, chiefly common colds, in a chil constitutes an indication for tonsillectomy continues to receiv a variety of answers. This study is based on observations mad of a group of Cleveland families during the period 1948 to 1952 Approximately 230 children were under observation for varying lengths of time. Daily records of the health status of each person were kept by the mothers. The families were visited weekly by field workers, and at the time of illness the patient was examined by a staff physician, who evaluated the illness and obtained throat cultures and other specimens as indicated.

The mothers' records, together with observations by the field workers and physicians, provided the data for this study. Two orts of data are presented. In the first place, the occurrence f the common respiratory diseases among all children of the amily population 3 years of age and older is considered separately for those whose tonsils had been removed and for those whose tonsils were intact; no child under 3 years of age had had tonsillectomy. Secondly, the occurrence of these illnesses mong 26 children who had a tonsillectomy while under study s shown, both for the period of observation before and for he period after operation. It was found that attack rates for he common respiratory diseases among children who had had a onsillectomy were very similar to those among children of comparable age who had not had this operation. There was no ndication of a difference in type of common respiratory disease between the two groups of children. The 26 children who had a tonsillectomy while under observation were found to have had a higher than expected rate of common respiratory disease both before and after operation. Tonsillectomy did not materially alter this incidence.

UROLOGY

Treatment of Acute Traumatic Renal Insufficiency. C. E. Catow. J. Urol. 73:913-920 (June) 1955 [Baltimore].

The clinical management of acute renal insufficiency has improved owing to research carried on during the Korean war on patients with lower nephron nephrosis. The author correlates some of the facts learned while observing the treatment of 50 patients in the Korean war plus a limited experience gained n private practice. He feels that the term acute tubular nephrosis as suggested by Moon more accurately describes the pathological picture; however, the term lower nephron nephrosis has entered medical terminology and will probably remain. The syndrome of acute renal insufficiency may be induced by the following causes: prolonged shock from any cause, trauma, hemoglobinemia, bacterial or chemical toxins, sensitization reactions, radiation, and anoxemia. Whatever the cause, the pathological picture and clinical course are essentially the same. Pathologically there is cloudy swelling and necrosis of the nephron, with the most marked changes in the tubular system. There is precipitation of myohemoglobin, hemoglobin, and other proteins within the tubules, probably producing a mechanical blockage to the flow of urine. The clinical course consists of the oliguric phase lasting about 10 days and the diuretic phase that extends over several weeks. During the former there are profound metabolic changes: elevation of nonprotein nitrogen, acidosis, hyperphosphatemia and reciprocal hypocalcemia, accumulation of toxic metabolites, and, most important, hyperkalemia. The mechanism of hyperkalemia deserves emphasis because of its dire effects and the special efforts required to combat it. Sources of the increased potassium in the blood are: tissue breakdown from extensive wounds, infections, and hematomas; catabolic mechanisms incident to diminished caloric intake; and acidosis with the resulting ionic shift of potassium from the cells to the extracellular fluid. The diuretic phase is characterized by electrolyte depletion and, therefore, continued vigilance is necessary. The nonprotein nitrogen remains high for a long time. These unusual changes are no doubt due to faulty absorptive mechanisms in the regenerating epithelium. Death, when it does not occur from associated wounds or overwhelming infections, may result from pulmonary edema due to overhydration or cardiac arrest secondary to hyperkalemia. The care of these patients is difficult, tedious, and trying, but, once the critical oliguric phase has been overcome, the kidney will probably be restored to normal. This regenerative capacity justifies all efforts. The regulation of the fluid intake deserves special attention during treatment, and it is especially important not to overwhelm the patient with fluid that cannot be excreted. Other important factors are: regulation of acid-base balance; maintenance of caloric intake; small frequent blood transfusions to control anemia and restore depleted proteins; antibiotics and vitamins; dialysis, by means of the artificial kidney in severe cases; and the control of hyperkalemia. Emphasis is placed upon the use of electrolyte antagonists to potassium and particularly the use of adequate amounts of sodium. The author suggests that an osmotic diuretic might be added to Red Cross blood in order to maintain glomerular filtration during the first critical hours of shock after injury; this might possibly prevent the mechanical blockage of tubules by precipitated proteins.

Ureterosigmoidostomy: Collective Review of Results in 2,897 Reported Cases. B. G. Clarke and W. F. Leadbetter. J. Urol. 73:999-1008 (June) 1955 [Baltimore].

The results obtained with four different types of ureterosigmoidostomies are evaluated. Better methods of anesthesia, blood and fluid replacement, intestinal intubation, and antibiotic therapy have permitted more extensive operations and have reduced the need for staged procedures. A clearer understanding has developed of disturbances in electrolyte balance that may occur after diversion of urine into the bowel. The authors present a collective review of 2,897 patients in whom the following four types of operations were performed: (1) a muscularizing operation, (2) direct anastomosis, (3) submucosal tunnel operation, and (4) a combination of submucosal tunnel with direct ureterointestinal anastomosis. Operative mortality varied widely but ureterosigmoidostomy appeared to be quite safe when not combined with pelvic cancer surgery. Pyelonephritis was less common after the combined operation than after other types. Hydronephrosis was less common after the combined operation. Air reflux from the intestine into the ureter was seen by x-ray in 17.5% of the patients in whom a direct anastomosis had been made. It was not observed after tunnel or combined types of operation. Hyperchloremic acidosis occurred in about a third of cases irrespective of type of operation. Analysis of a small group of patients operated on by the combined technique indicated that this complication did not occur in the presence of a postoperatively normal upper urinary tract.

Optimum Time for Orchiopexy in Cryptorchidism. F. Hinman Jr. Fertil. & Steril. 6:206-214 (May-June) 1955 [New York].

Biopsy specimens from undescended testes were compared histologically with normal testes from children of similar ages. The authors found that the undescended testis may be just one manifestation of congenital malformation or of endocrine dyscrasia. Many testes are constitutionally so abnormal that they will not function no matter what sort of hormonal or operative therapy is applied. If the testes are potentially normal, surgical placement must be performed before they are irreversibly damaged by the high intra-abdominal temperature. Physical abnormalities in the testis or primary endocrine abnormalities prevent descent of the testis. The decision for or against treatment of cryptorchism should be made between the ages of 3 to 6 years, because after 6 years, irreversible damage has usually occurred. Giving methyltestosterone linguets will show what effect puberty will have, without the need for waiting while irreversible changes take place. In unilateral cryptorchism, nondescent usually means obstruction, so hormones will seldom be effective. In this condition orchiopexy is the only effective treatment, since the patient's own pituitary hormones have proved sufficient to bring down the testis on the opposite side. Operation is also necessary if the retained testis is associated with a clinically demonstrable hernia. If hormonal stimulation fails, surgery is indicated. Hormones have made orchiopexy easier by enlarging the testis and its adjacent structures. The decision between orchiopexy and orchiectomy will usually be made at the operating table, by consideration of the appearance of the testis and the technical difficulties in bringing it completely within the scrotum. There is little chance for spermatogenesis unless the testis is reasonably normal in development, has not been too severely damaged by staying overlong in the abdomen, and can be brought completely within the scrotum. Tumor of the testis is 20 times more frequent in patients with cryptorchism, so there is an additional argument for either bringing the testis to a site where it can be followed by palpation, or removing it if it appears too maldeveloped to produce an effective number of sperm. Since the retained testis may be irreversibly damaged well before puberty, hormonal stimulation should be tried before the age of 6 years. If it fails, orchiopexy should be performed at once. Many failures can be explained by congenitally defective testes or general endocrine abnormality and are not necessarily the result of the operation.

Diverticula of the Female Urethra: Review, New Procedure for Treatment, Report of Five Cases. E. A. Edwards and R. A. Beebe. Obst. & Gynec. 5:729-738 (June) 1955 [New York].

The mode of origin of diverticula of the female urethra is still uncertain. These diverticula may be congenital or acquired. Conservative or radical treatment can be used, but most investigators prefer the radical methods. All agree that there is likelihood of urethrovaginal fistulas if the diverticular sac is not wholly excised. The authors' surgical technique, which has not been previously reported, consists of separating the vaginal mucosa and fascia overlying the diverticulum and floor of the urethra. The urethra is incised from the external urethral meatus to the site of the opening of the diverticulum into the urethra (provided this is within the distal two-thirds of the urethra). The diverticulum is then excised. The urethra is repaired over a catheter placed in the urinary bladder through the proximal third of the urethra, which has not been incised. There is no interference with urinary continence by this method. Five patients have been treated successfully in this manner and followed for from 3 to 13 years. There have been no failures.

OTOLARYNGOLOGY

Current Medication in Otitis Externa. G. E. Tremble. A. M. A. Arch. Otolaryng. 61:629-637 (June) 1955 [Chicago].

Cultures from patients with diffuse external otitis showed the Pseudomonas aeruginosa to be the chief causative agent. In relatively few ears were gram-positive bacteria such as Micrococcus (Staphylococcus) aureus and albus or nonhemolytic Streptococcus cultured. Although some of the newer antibiotics are effective against many gram-negative and most of the gram-positive organisms, Ps. aeruginosa seems to be the exception. In view of the fact that over 65% of cases of external otitis are due to this organism alone or in combination with some form of Streptococcus, one single drug would not appear to be sufficient. Of all the antibiotics, oxytetracycline orally would seem the most effective to get rid of the gram-negative rods, and sulfadiazine or triple sulfonamides, to take care of the gram-positive Streptococcus organisms. Experience has shown that many patients with external otitis refractory to other forms of therapy responded to 4-amino-2-methyl benzene sulfonamide hydrochloride (Sulfamylon, also known as Marfanil or Mesudin): Sulfamylon in 1% to 4% solutions seemed equally effective, although the weaker solutions required a longer time. Polymyxin B has recently proved effective in otitis externa. It destroys Ps. aeruginosa and is also bactericidal to some gram-positive organisms, including Micrococcus and Streptococcus. It also kills certain fungi and can be given intramuscularly as well as by local application. It is now thought that less than 15% of cases of external otitis are caused by fungus infection. Metacresylacetate is fungicidal and has a local analgesic effect. Dibromosalicylaldehyde solution is effective against gram-negative organisms and fungi. Coparaffinate (Iso-Par) ointment is an effective fungicide and bactericide. Recently acetic acid has been added to many of the drops used for external and middle ear infections. Aluminum acetate with acetic acid (Burrow's solution) is an old-fashioned remedy for otitis externa that has stood the test of time. Another agent present in many of the ear drops currently advertised is urea. Among the ear drops that contain urea are Otosmosan (a liquid containing 20.5% sulfathiazole carbamide incorporated in dehydrated glycerol), Glycerite of Hydrogen Peroxide, and Otomide (a solution containing carbamide, sulfanilamide, glycerin, and chlorobutanol). Ethyleneglycolmonophenylether (Phenoxetol, 2.2%) has been used successfully in otitis externa associated with Ps. aeruginosa infection. A commercial preparation, Neo-Cortef, cortisone acetate with neomycin sulfate sterile suspension, has proved successful in many refractory cases of otitis externa; usually the inflammation, exudation, and itching tend to subside within a few days, but occasionally patients have to use the drug for months. In the treatment of patients who ha otitis externa, unless the underlying cause, such as allergi physical, chemical, endocrine, psychosomatic, and emotion factors, is corrected, there are likely to be recurrent cases this condition.

Vocal Palsies in Children. F. Cavanagh. J. Laryng. & Ot 69:399-418 (June) 1955 [London, England].

The author has observed a number of babies suffering fro so-called congenital laryngeal stridor and has performed 1 laryngoscopies on 107 children. Vocal palsies were found 37, congenital laryngeal stridor in 24, no lesions in 11, su glottic edema (allergic and chronic inflammatory) in 11, pap lomas in 6, vocal nodules in 6, aggressive false cords in 5, scal and corrosive poisoning in 3, congenital web in 2, foreign bo in the larynx in one, and nevus in one. Most of the vocal palsi were unilateral but 10 were bilateral. A surprising fact is th in the unilateral group 23 were on the right and 4 on the le Some cords were completely paralyzed and others only partia paralyzed. There was wide variation in the degree of impro ment, as well as in the time required for any recovery. In thr children who were recovering from unilateral paralysis, t author observed that during moderately quiet breathing the i paired cord showed no movement, though the normal one ducted regularly to a uniform degree. If deeper breathing induced, the good cord abducted further and made three four excursions before the weak cord moved once, and wh the weak cord had made one abduction it would often lie ag in the midposition while the normal cord abducted anot three or four times. At one examination in a little girl, good cord always gave three abductions before the weak moved, and, in a small boy, the normal cord repeatedly ducted five times for each abduction of the recovering c In the third child the pattern varied; there were sometimes t three, or four abductions on the healthy side for one of affected cord. Several patients have been observed for five seven years. The seriousness of the vocal palsies is shown by fact that 11 of 37 children needed tracheotomy—and in these the operation was necessary in the first half year of l Five of the children who were subjected to tracheotomy d A funnel deformity of the lower end of the sternum develo in 10 of the babies. In only 8 of the 37 patients was it possi to find a causal factor. The tomogram can be used to dem strate vocal paralysis after the age of 5 years.

THERAPEUTICS

Clincial Studies on a Vasopressor Agent: Metaraminol (A mine): I. Observations in Normotensive Subjects. M. H. W and W. W. Spink. Am. J. M. Sc. 229:661-669 (June) 1 [Philadelphia].

Although it is unlikely that any sympathomimetic agent have all of the desirable attributes, available information s gested that metaraminol (Aramine) approximated the id agent more closely than did other more commonly used pres agents. The authors observed normotensive volunteers, beca it is difficult to interpret observations made during the st of shock in human subjects. Single subcutaneous, intramuscul or intravenous injections of metaraminol were given on 51 oc sions to 31 subjects. All of the volunteers were normotensi young men free of demonstrable cardiovascular disease. Bef injection they were told to report all subjective effects that f lowed. Their blood pressures were measured while they we supine. After a period of rest, and following two control rea ings before administration of the drug, the blood pressure a pulse rate were measured at 1 to 5 minute intervals short after the injections and at 5 to 15 minute intervals if the dr caused a prolonged effect. It was found that metaraminol m be effectively given subcutaneously, intramuscularly, or intr venously without demonstrable injury to the tissues at the si of injection. A prompt and potent vasopressor response m be obtained with a single intravenous injection of 3 to 10 m of the drug. Subsequent maintenance of blood pressure may secured by the intravenous infusion of 30 to 200 mg. of m taraminol per liter of fluid. When the blood pressure has been sustained, subsequent support may be afforded by single subcutaneous injections of the drug. A prolonged effect may be achieved by intermittent subcutaneous or intramuscular injections of metaraminol. The authors conclude that the drug is a potent pressor agent and is nontoxic.

Direct Arterial Study of the Blood Pressure Response to Cold of Normotensive Subjects and Patients with Essential Hypertension Before and During Treatment with Various Antihypertensive Drugs. J. H. Windesheim, G. M. Roth and E. A. Hines Jr. Circulation **11**:878-888 (June) 1955 [New York].

The cold pressor test was performed three times at 15 minute intervals on 65 volunteers with normal blood pressure and on 60 patients with essential hypertension. The study was repeated in some of the controls in one to five months and in all patients with hypertension in about three weeks. The arterial pressure was recorded directly from the radial artery. In this study, the cold pressor test proved a reliable index of vasomotor reactivity, both of persons with normal blood pressure and of patients with hypertension. Repetition of the test at short and long intervals yielded consistently constant responses of blood pressure for each person. The response did not seem to change with age, although only seven patients of more advanced age (between 41 and 62 years) were included in the control group. The time between immersion of the hand in ice water and the maximal blood pressure was between 50 and 60 seconds in most of the controls and patients with essential hypertension. Therefore, the indirect reading most likely to give the true maximal blood pressure should be made at this time. The response to the cold pressor test was considered abnormal if the increase in the diastolic pressure in response to cold was 15 mm. Hg or more and if the maximal diastolic pressure was 85 mm. Hg or more by the direct arterial method of blood pressure recording (90 mm. Hg or more if measured by the indirect method). Persons with normal basal blood pressure whose diastolic pressure rose more than 15 mm. Hg but whose maximal diastolic pressure was less than 85 mm. Hg by direct measurement were included in the group of normal reactors. With these criteria, 46 (70.8%) of the 65 controls were considered to be normal reactors and 19 (29.2%) normal hyperreactors. The 60 patients with essential hypertension were studied before treatment with various antihypertensive drugs was begun and while under treatment of the hypertension, in order to evaluate the effect of the various antihypertensive drugs on the cold pressor response. The response of their blood pressure to cold before treatment was uniformly greater than that of the controls except among those with the most severe hypertension. It is likely that the vessels of the latter could not constrict more under the added stimulus of cold, since they were already maximally constricted. The ganglionic blocking agents, hexamethonium and pentapyrrolidinium, markedly depressed the response to the cold pressor test, and this observation appeared to be clinically significant. Hydralazine hydrochloride combined with hexamethonium possibly aided in the depression of the pressor response to cold. Protoveratrine, reserpine, and hydralazine in various combinations had no effect on the cold pressor response. That the load placed on the heart by the activity during treatment was greater in the patients with the less severe hypertension than in those with severe hypertension is suggested by the fact that, in the patients with severe hypertension, who were treated with ganglionic blocking agents, basal blood pressure and the cold pressor response were reduced, and hence they had lower maximal pressure during activity than did the patients with milder hypertension, who were treated with the other drugs. Thus the ganglionic blocking agents would appear to have a clinical advantage over the other agents.

Undesirable Side-Effects of Dissolved Pyrazol Bodies in Treatment of Rheumatic Fever. W. Falk and E. Sekol. Wien. klin. Wchnschr. **67**:393-397 (June 3) 1955 (In German) [Vienna, Austria].

In 1953 and 1954, a hemorrhagic diathesis developed in seven children between the ages of 6 and 12 years with acute polyarthritis and rheumatic endocarditis, respectively, in the course of their treatment with Irgapyrine (a proprietary compound containing equal parts of phenylbutazone and aminopyrine), and with Butazolidin (a proprietary preparation of phenylbutazone). Four of the seven children had hematuria, and the three others had hemorrhages of the skin and mucosa. The general condition was poor in only one patient, who had a very low thrombocyte count, although the mechanism of coagulation was not disturbed otherwise. In an attempt to elucidate the side-effects, and particularly the thrombocyte-damaging effect, of the three antirheumatic drugs given to these patients, the effect of Irgapyrine, Butazolidin, and aminopyrine on the blood of rats was studied. Results showed that Irgapyrine, Butazolidin, and aminopyrine exert a mild anemizing effect in rats, but no influence on the leukocytes was noted. Butazolidin, and aminopyrine even more, caused a drop of thrombocytes in the peripheral blood of the rats. Although an undesirable side-effect of Butazolidin and aminopyrine in the sense of thrombopenia was observed in the authors' pediatric patients and in the animal experiments, this does not seem sufficient to explain the development of hemorrhagic diathesis. It is suggested that the hematuria, as well as the hemorrhages of the skin and of the mucosa, in the authors' patients were manifestations of vascular impairment, which most likely was of toxic-allergic type.

Clinical Study on Weight Reduction in Obesity. H. Sapoznik. Am. J. Digest. Dis. **22**:159-160 (June) 1955 [Fort Wayne, Ind.].

Six different formulas of reducing compounds were given a trial in obese patients in order to induce decreased food intake and permit weight reduction. All patients were asked to use 1,000 calorie diet containing approximately 100 gm. of carbohydrate, 20 gm. of fat, and 100 gm. of protein. Amphetamine (Benzedrine) or a proprietary preparation of *d*-amphetamine (Dexedrine), by themselves or in combination with thyroid hormone, produced not only loss of weight but also undesirable side-effects such as nausea, epigastric distress, nervousness, insomnia, dizziness, headaches, palpitations, and constipation. The best reducing combination was a proprietary preparation (Obolip), which contains only a small dose of *d*-amphetamine, a small dose of phenobarbital, lipotropic factors, vitamin B_{12}, and methylcellulose. With this compound mild side-effects, including insomnia, nausea, and epigastric distress, were noted in only 2 of 15 patients. An average weight loss of 3 lb. (1.3 kg.) per week in a six week course of treatment with this drug was obtained. The fact that drugs containing a central nervous system stimulant, such as the amphetamine derivatives alone or in combination with thyroid extracts, did not produce the desired results in weight reduction without undesirable side-effects is in contrast to the reasonably uniform and predictable manner in which the reducing agent containing lipotropic factors for the treatment of infiltration of the liver appeared to work. Thus, the claim of a metabolic approach to obesity made for Obolip was supported by clinical experience.

Tetracycline. R. L. McCorry and J. A. Weaver. Lancet **1**:1102-1105 (May 28) 1955 [London, England].

The structure and antimicrobial spectrum of tetracycline (Achromycin) are similar to those of chlortetracycline and oxytetracycline. All three substances have the same chemical nucleus. Other investigators have observed that tetracycline is as effective therapeutically as the other two preparations and may have certain advantages over these. The authors investigated the clinical usefulness of tetracycline in 87 patients. The sensitivity of pathogenic organisms, isolated from patients in the hospital, to tetracycline was also studied. Minimal inhibitory concentrations of tetracycline for 71 strains of common pathogens are listed. These common pathogens included among others Micrococcus (Staphylococcus) aureus, Streptococcus pneumoniae, Str. hemolyticus, Str. viridans, Escherichia coli, and Friedländer's bacillus. Tetracycline proved effective against both gram-positive and gram-negative organisms. Most of the 87 patients were treated for acute infections of the respiratory system. The clinical response was assessed on the duration of pyrexia, subjective improvement, and objective physical and radiological findings. In pneumococcic lobar pneumonia the results obtained were good and in every respect equal to those after the use of chlortetracycline and oxytetracycline. In acute bronchopneumonia the results were variable and difficult to assess, owing to many other complicating disease processes being present; e. g., cardiac failure. Drug treatment was of necessity started before sputum results were available. Three patients in this group had on admission been started on penicillin therapy without response, and culture of the sputum showed the predominant organism to be Friedländer's bacillus in two of these cases and Hemophilus influenzae in the third. When the treatment was later changed to tetracycline the improvement was dramatic. Generally the results were comparable to those observed with the two analogues. In 10 of 39 patients with pneumonia the results were less than expected. There was a temporary improvement with lessening of the amount of sputum in six of the eight patients with bronchiectasis. The favorable outcome in most of the small number of patients with miscellaneous infections compares with results obtained with the two analogues. The side-effects resulting from tetracycline therapy were mostly gastrointestinal, and their incidence as regards diarrhea was somewhat less than with the two analogues, particularly as regards nausea. The fact that resistant organisms are less likely to develop with the tetracyclines than with penicillin has encouraged some workers to recommend the universal use of the tetracyclines in acute chest conditions. This advantage is somewhat offset by the quicker action and lesser side-effects of penicillin in the infections with sensitive organisms, and for that reason the authors believe that penicillin should still remain the drug of choice in the initial treatment of pneumonia and that tetracycline should be reserved for patients who do not respond to penicillin, or in whom the causal agent has been shown to be penicillin-resistant.

PATHOLOGY

Lung Biopsy in Diffuse Pulmonary Disease. P. A. Theodos, F. F. Allbritten and R. L. Breckenridge. Dis. Chest **27**:637-648 (June) 1955 [Chicago].

Lung biopsy under direct visualization through a small incision was performed with the aid of local anesthesia and with the lung kept expanded by positive pressure oxygen given through a snugly fitting face mask in 50 patients with diffuse pulmonary lesions. In 27 patients, a specific diagnosis was established by histological and bacteriological study of the biopsy specimen. In 26 of the 27 patients, the preoperative diagnosis was confirmed by biopsy. Lung biopsy is of greatest value in diffuse lesions such as those seen in pneumoconiosis, sarcoidosis, metastatic malignancy, and tuberculosis, where a specific pathological entity is present. In these conditions the diagnosis can be readily established, since the abnormal findings are sufficiently well-defined to permit accurate diagnosis. No specific pathological diagnosis was possible in 23 patients. Biopsy served only to rule out the presence of a definite disease entity in these patients. Appreciation of the high prevalence of nonspecific fibrosis and emphysema in clinical practice should make the use of lung biopsy more selective. The procedure was well tolerated by the authors' patients and produced minimal complications, except in one patient who died of cardiac failure secondary to pulmonary insufficiency three days postoperatively. In general lung biopsy affords a rapid, accurate method for diagnosis, determination of the medicolegal status, and determination of the prognosis of diffuse pulmonary lesions. The use of the procedure as a diagnostic aid shortens the period of hospitalization and lessens the cost.

Lipoid Pneumonia Due to Prolonged Ingestion of Mineral Oil. J. B. Meyers and R. L. Griffith. Dis. Chest **27**:677-684 (June) 1955 [Chicago].

Of 355 autopsies performed between 1949 and 1952, 7 (2%) revealed lipid pneumonia as a complicating or concomitant disease in men between the ages of 30 and 74 years who had some serious illness other than lipid pneumonia which was primarily responsible for their deaths. In three of these cases, however, lipid pneumonia was listed as the immediate cause of death, in one case lipid pneumonia was considered to be an important contributory cause of death, and, in the remaining three, lipid pneumonia was an incidental but definite finding. All of the patients had used mineral oil regularly as a laxative. One patient wit a stricture of the esophagus caused by swallowing lye in earl childhood also employed mineral oil to lubricate the bougie used to dilate his esophageal stricture. In one of the cases microscopic examination of the lung revealed a granulomatou proliferative inflammatory process caused by the mineral oil in a case of this type the term chronic pulmonary oleosis seem more appropriate than lipid pneumonia.

Analysis of Focalized Pulmonary Granulomas Due to Coccidioides Immitis. R. L. Alznauer, C. Rolle Jr. and W. F. Pierce A. M. A. Arch. Path. *59:641-655 (June) 1955 [Chicago].*

The "coccidioidal pulmonary residual" is an all-inclusive term applied to the different types of focalized lesions remaining i the lung parenchyma, either temporarily or permanently, afte the resolution of the acute pneumonitis due to the fungu Coccidioides immitis. These focalized lesions can be divided int three major groups: (1) the solid fibrocaseous granuloma, (the fibrocaseous granuloma with cavitation, and (3) the linea fibrotic scar. This paper is concerned with the first two typ of focalized lesions, since the third represents the final sta in healing, and probably has no clinical significance. The autho observed 11 patients with fibrocaseous granulomas of the lun due to C. immitis. All were men, ranging in age from 21 47 years. Six patients probably had acquired their prima coccidioidal infection in southern California, one in the Sa Joaquin Valley, and four in Arizona. In four asymptomat patients, solid lesions were discovered by routine roentgen grams of the chest. None of these had had a history of an acu pneumonitis suggestive of the primary infection with C. immiti Despite thorough clinical investigation, the exact nature of the solitary pulmonary nodules could not be established with ce tainty, and hence they were surgically resected, three by l bectomy and one by wedge resection. Five of the seven patien with cavities had a history of an acute pneumonitis. Althou the possibility of an acute coccidioidal pneumonitis was cli cally suspected at the time, a definite diagnosis by means positive sputum cultures had not been established. Subsequent these patients had sporadic episodes of cough, hemoptysis, lo grade fever, and related symptoms, as well as radiological e dence of a persisting cavity for periods of 4 to 30 mont Although the sixth patient never had a history of an acute pne monitis, subsequent cough and hemoptysis led to medical inv tigation, with discovery of the cavity by chest x-ray. The seve patient never had a history of an acute pneumonitis and w asymptomatic at the time of discovery by routine chest x-ra Wedge resection of the cavity was performed in all seven p tients. All 11 patients were discharged from the hospital either full duty or to civilian status. The coccidioidin skin test was po tive in all 11 patients. Eight also had positive skin reactio to histoplasmin, tuberculin, or both. Coccidioidal compleme fixation tests were performed. The serologic titers were consi ered to be diagnostic of coccidioidal infection in six patien equivocal in one, and negative in the remaining four. The fi patients with either a negative or equivocal serologic test al had positive skin reactions to histoplasmin, tuberculin, or bot Under these conditions, the diagnosis can be made only by t demonstration of the causal organism. The coccidioidal pulm nary residual is not necessarily stabilized; if patent communic tion with an adjacent bronchus is established, a solid granulom may become a cavitary lesion after the evacuation of its caseo contents. This occurred in one of the reported cases. Conversel a cavitary lesion may be converted to a solid granuloma becau of obstruction of its communicating bronchus followed by i spissation of its contents due to the reabsorption of fluid. Despi such occasional mechanical fluctuation in its structure, th coccidioidal pulmonary residual is a relatively bland and innoc ous lesion.

A Clinico-Pathological Study of Diabetic Glomerulosclerosi A. T. Lambie and A. Macfarlane. Quart. J. Med. **24**:125-14 (April) 1955 [London, England].

This study is based on 120 consecutive cases of diabetes mel litus, which came to postmortem examination in the years 195 to 1954 in the pathological service of Edinburgh University The typical glomerular lesion (Kimmelstiel-Wilson lesion) con sists of a focal deposit of hyaline material in the center of a glomerular lobule. Fifty-five of the 120 patients (46%) showed evidence of diabetic glomerulosclerosis, it being slightly more common in women than in men. The 55 cases were graded according to the number of glomeruli involved. Twenty-three patients had grade 1 lesions, that is, less than 25% of the glomeruli were involved; 9 had grade 2 lesions (26 to 50% of glomeruli involved); 9 had grade 3 lesions (51 to 75%); and 14 had grade 4 lesions (over 75% of the glomeruli involved). Poor diabetic control seems to be a factor in the development of this lesion, since it was considerably more common in poorly controlled diabetes. The average duration of diabetes in patients with glomerulosclerosis was 11.7 years and in those without the lesion 7.3 years. The severity of glomerulosclerosis is also related to the duration of the diabetes. Glomerulosclerosis is found most often in patients in the seventh and eighth decades, but the majority of cases of diabetes, with or without renal lesions, also occur in these age groups. In most decades, however, the incidence of the lesion is approximately 50%. The incidence of glomerulosclerosis does not bear any relation to the severity of the diabetes. There were 11 patients with the fully developed clinical syndrome of albuminuria and nephrotic edema. There was no constant histological pattern in the renal glomeruli in these patients. Massive albuminuria appears to be related to the presence of exudative lesions in the glomeruli. Most patients with mild glomerulosclerosis do not show clinical evidence of its presence, and even seven cases of severe glomerulosclerosis were not clinically obvious. Young diabetic patients with glomerulosclerosis have clinical evidence of the lesion more commonly than do elderly diabetics.

Newer Concepts of Experimental Obesity. M. B. Fertman. A. M. A. Arch. Int. Med. 95:794-805 (June) 1955 [Chicago].

A distinction should be made between obesity, a severe, often irreversible disease, and simple overweight, reversible and based on a high ratio of caloric intake to activity or to rate of growth. Obesity takes many forms and is the end-result of various interacting factors, extrinsic and intrinsic. The extrinsic causes of obesity include excessive caloric intake, and perhaps nutritional deficiencies as well; relative inactivity; toxic effects; and possibly stress situations. The extrinsic factors may bring certain of the intrinsic causes of obesity into operation. The intrinsic causes include the constitutional, the diencephalohypothalamic, the endocrine metabolic, and the enzymatic. All of these may be interrelated and interactive. Anywhere along the pathways of the numerous intricate reactions of carbohydrate-fat metabolism, of fat mobilization, and of fat deposition, a disturbance might occur that conceivably could lead to obesity. There is now experimental evidence that in the form of obesity that follows infection or injury, the pancreas is involved. Although perhaps less conclusive, results indicate also that other endocrine glands, the adipose tissue, and enzyme systems play at least a partial role. That hyperphagia or inability to recognize satiety may lead to obesity is demonstrated by experiments with hypothalamic-induced lesions or stimulation. Again, metabolic factors may be concurrently involved.

RADIOLOGY

Radiotherapy in the Management of the Cancer Patient. G. H. Fletcher. Postgrad. Med. 17:490-497 (June) 1955 [Minneapolis].

Physical science has developed a variety of means of delivering ionizing energy: low energy x-rays (45 kv.) used in skin cancers; deep roentgen therapy (200 to 250 kv.); million-volt machines (1 to 2 mev.); cobalt-60 teletherapy (3 mev. equivalent); ultrahard x-rays produced by betatron or linear accelerators; and many gamma ray (x-ray) or beta ray (electron) isotope emitters. This broad spectrum of ionizing tools has increased the range of attack on malignant growths. Radiation produces biological changes through the process of ionization. The radiocurability of certain types of cancers is made possible by the margin of radiosensitivity between tumor cells and normal supporting structures, but radiosensitivity and radiocurability are not identical terms. Tumors such as the lymphomas are very radiosensitive, but rarely radiocurable, because they either generalize quickly, or are a generalized disease to begin with. Keratinizing, squamous cell carcinomas, on the other hand, require very high doses of radiation that approach the limit of tolerance of the supporting structures. Indications for radiotherapy are by no means simple, because it may be a truly curative procedure, or only palliative; and it may be combined with surgery or used alone. If the cancer is radioresistant, as the neurogenic sarcomas and adenocarcinomas of the gastrointestinal tract are, there is no problem since operation is the sole method of treatment. If the tumor is extremely radiosensitive, and probably a generalized disease from the beginning, such as the lymphomas, radiation is undoubtedly the treatment of choice. When one is dealing with squamous cell carcinomas that are amenable to both radiation and operation, there are many determining factors in the selection of treatment. A patient may be in worse condition after an ill-advised course of radiotherapy than he would be in had he not been treated. Radiation necrosis superimposed on growing cancer is more painful than cancer alone. However tempting it is to the physician to do something for the hopeless patient, the greatest kindness is not always to use aggressive therapy.

ANESTHESIA

Chlorpromazine Hydrochloride in Intraocular Surgery. A. B. Nutt and H. L. J. Wilson. Brit. M. J. 1:1457-1458 (June 18) 1955 [London, England].

Eighty patients between the ages of 18 and 80 years who underwent intraocular surgery were anesthetized as follows. One hour preoperatively 0.1 gm. of secobarbital (Seconal) was given by mouth and 100 mg. of meperidine (Pethidine, Demerol) hydrochloride intramuscularly; in some frail patients the secobarbital was omitted. Fifteen minutes before the start of the operation, an intravenous injection of a mixture of 50 mg. chlorpromazine (Largactil) hydrochloride and 100 mg. meperidine hydrochloride diluted to 20 cc. with sterile water was given slowly at the rate of about 1 cc. per minute until the patient fell asleep and could tolerate a lubricated artificial airway. The dose required varied from 20 to 45 mg. of chlorpromazine and 40 to 90 mg. of meperidine. A regional infiltration with procaine was given, coupled with a retrobulbar injection. The patient slept peacefully throughout the operation and the surgeon took as long as he wished without the fear of a restless patient. Of the 80 patients, 60 underwent cataract operations, and 20, operations for glaucoma and corneal grafting. There were no deaths or morbidities, and the patients' postoperative condition was excellent. Although the method was not used in extremely frail patients and those with severe cardiac disease, it was employed in nervous patients and in many with signs of arteriosclerotic cerebral degeneration in whom a purely local technique would have been dangerous. The main advantages of the method are: (1) no cooperation is required from the patient during the operation and for several hours afterwards; (2) it produces a low-tension eye, ideal for intraocular surgery; and (3) the recovery period is extremely quiet and uneventful.

Arterial Pressures in the Extremities of Normal and Hypertensive Persons. M. Riser, J. Planques and A. Couadau. Presse méd. 63:987-989 (June 25) 1955 (In French) [Paris, France].

The authors determined normal arterial pressures for wrists, fingers, ankles, toes, and temporal arteries in various postures and found that in a normal man lying flat the temporal pressure is lower than that in any other peripheral artery, namely 40 mg. Hg. This difference increases in the sitting and standing positions because the pressures in the limbs increase and that in the temporal artery decreases to 35 mm. Hg. The rise in pressure in a hanging limb is generally accompanied by a lasting rise in the oscillometric index. In hypertensive persons the pressure does not rise everywhere in the extremities proportionally to the humeral hypertension. The temporal pressure and the retinal pressure (as measured by Bailliart's method) increases relative to its normal amount more than the pressure in the extremities does relative to its normal amount. This explains the cephalic affinity of the hemorrhage and edema of arterial hypertension.

QUERIES AND MINOR NOTES

PROGRESSIVE MUSCULAR DYSTROPHY

To the Editor:—*I would like information on the use of adenosine triphosphate in the treatment of progressive spinal muscular atrophy.* *M. J. Pond, M.D., Kirksville, Mo.*

Answer.—Some doubt exists in regard to the exact disease referred to. Progressive muscular atrophy is an intrinsic, degenerative disease of the motor system, the anterior horn cells, and sometimes the corticospinal tracts. Usually developing late in life, the disease does not show a hereditary tendency. No form of treatment is known that will change the progress of this disease, as the muscular atrophy is secondary to the nerve cell destruction, and regeneration of nervous tissue is not possible. A fatal termination is to be expected in two to eight years. On the other hand, progressive muscular dystrophy, to which the query probably refers, is a primary degenerative disease of the skeletal muscles rather than of the nervous system. There is a possibility of some regenerative activity in muscle, particularly in dystrophy from deficiencies in vitamin intake content or secondary to virus infection. Unfortunately, this is not the most common type of dystrophic disorder. The more usual type is a hereditary form of dystrophy occurring early in childhood. The muscles may show either pseudohypertrophy and thus appear larger than normal, or they may be smaller and thus become clinically atrophic. Although the final stage of muscular degeneration in the dystrophies is not dissimilar to the atrophy seen when a muscle is deprived of its nerve cell or cut off from its supporting influence, the earlier stages of muscular dystrophy are quite dissimilar to those found in progressive muscular atrophy. There is a preliminary enlargement of the muscle fiber and granular and fibrillary changes in the myofibrils, suggesting a primary defect in the muscle itself. As it is not uncommon in dystrophy to find muscle fibers small but otherwise normal in appearance, it has been assumed that the defect, in part, may be one of maturation of muscle fibers and their supporting tissue. In other words, the fault may be in the muscle nucleus, thus interfering with the normal production of myofibrils.

These and other histological observations have led to attempts at stimulation of muscle cells by chemical means, such as the use of adenosine triphosphate to compensate for defects either in the nucleus or in the muscle fiber itself. It is still to be proved, however, that adenosine triphosphate is the immediate source of energy in the contracting muscles. Indeed, there is some evidence that muscles can in fact do work without the decomposition of an equivalent amount of this drug. Added evidence against the value of adenosine triphosphate as a useful form of treatment is suggested by the failure of a continuous infusion into the brachial artery to show an effect on the amount or rate of blood debt repayment following rhythmic exercise of the forearm muscles. Progressive muscular dystrophy is sometimes confused with polymyositis, but the more rapid onset and the tendency to progress by remission and relapse in the latter disease should make a differential diagnosis possible. The pathological changes in muscles observed in polymyositis are different from those found in muscular dystrophy, so a muscle biopsy is a certain means of differentiation and should be obtained in every case. Those patients, moreover, who respond to treatment with corticotropin or wheat germ preparations are almost certainly examples of polymyositis. If adenosine triphosphate should also stimulate muscle response when used clinically, the possibility of polymyositis, instead of true progressive muscular dystrophy, must always be kept in mind. Adenosine triphosphate is primarily a vasodilator. It has been used in a large number of conditions, such as diabetic neuropathy, liver disease, rheumatic syndromes, heart failure, asthma, and allergy. Reports are not available that suggest the value of this drug in muscular dystrophy. Until further evidence is presented of a clinical nature, a high mineral diet, with yeast, is all that is indicated and even this may not affect the progressive course of muscular dystrophy.

TAKING PICTURES IN OPERATING ROOMS

To the Editor:—*I would like to inquire about taking electronic flash pictures in hospital operating rooms. I am using a Heiland Strobonar V outfit, which is a condenser type of discharge working from an entirely sealed battery. The flash bulb has an enclosed filament sealed in glass and is used for thousands of flashes without changing. I cannot see any danger in using this apparatus in the operating room but would like your opinion to present it to the local operating room committee and to the local fire department. If you consider this apparatus hazardous, please give instructions regarding the use of photographic apparatus that is being used in many operating rooms at present.* *Daniel M. Kingsley, M.D., Alexandria, La.*

Answer.—Electronic photoflash lamps should not be employed in operating rooms of hospitals unless careful precautions for safety are observed before using them. In the "Recommended Safe Practices for Hospital Operating Rooms" of the American Fire Protection Association, Section 8-2-b points out that smoking, open flames, hot materials, photoflash or photoflood bulbs, cautery equipment, high frequency devices, and electronic equipment such as amplifiers, recorders, television cameras, x-ray machines, and certain sterilizing machines introduced into the area of combustible gas accumulations create an extreme hazard to patients and hospital personnel. Section 2-2-d of the same "recommended standards" reads "In anaesthetizing location the hazardous location is to be considered to extend 5 feet above the floor." It is above this 5 ft. level that operating room surgical lights are installed. Although these lights are "explosion proof" photoflood lights can be placed more than 5 ft. above the floor too, which is considered outside the hazardous location. But the photoflood lights are less dangerous than the connecting wires that energize them. Poor connections, such as the extension cords that are strung on the floor to electrify the photoflood lights, are more likely to create the hazardous condition. It is especially true when faulty connections in the plugs permit electric arcs. A surgeon is at the threshold of inconsistency and will jeopardize the safety of his operating room, which is probably equipped with modern safety appliances, by allowing a careless photographer to use sloppy extension cords. Photoflash lamps have connecting wires and electric arcs that might create a hazard. The only true safety measure that would offer adequate protection in the hazardous location is expensive and cumbersome. Place the camera and electronic flash unit within a strongly sealed box similar to that used for undersea photography and pressurize the box with two or three atmospheres of an inert gas such as helium. The inert gas under pressure will exclude the explosive gas in the box. A transparent panel for the lens of the camera, the lamp head of the flash unit, the controls for operation of the camera, and the flash unit from outside the box must be provided. Installing the electronic flash lamp assembly according to these precautionary measures will render the equipment less dangerous and can be used within the hazardous level.

On the other hand, if the electronic flash lamp, including the electrical equipment for control of the shutter, is held and operated well above the 5 ft. level then the flash lamp may be used. Such a location might be in the balcony of an operating room in a teaching hospital. The camera might be equipped with a telescopic lens.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

INTUSSUSCEPTION

To the Editor:—*Five years ago the oldest of five siblings, at the age of 8, had acute abdominal pain, and, on exploratory laparotomy, an intussusception was noted and reduced. Another boy was operated on, in January, 1955, for an exploratory laparotomy because of recurrent abdominal pain, with symptoms of low grade obstruction. An intussusception of the ileum into the ileum was noted and an intestine resection was done. The patient had had the symptoms for three years. At the time of the operation this boy was 8 years old. The younger brother who is age 7 has had similar symptoms for two years and was explored on Feb. 18, 1955. At that time several portions of the ileum were noted to be dilated and extremely thin walled. However, the amount of intestine that would have had to be resected was too extensive, and it was decided to put the patient on medical therapy. What is your advice as to the type of therapy involved? What is the chance of this third patient to develop a localization with intussusception? Should they be considered congenital or hereditary?*

M.D., Montana.

Answer.—The type of therapy for the younger brother whose intestine was not resected would depend on an understanding of the conditions discovered at the time of operation and could not be very well discussed by a person not familiar with the case. However, a continuation of medical therapy would seem wise. A recurrence rate of 2% has been observed in a series of some 700 children who were operated on for intussusception. The finding of an extremely thin-walled ileum in the present patient suggests that a recurrence of the condition is more likely than would be expected in the absence of such a condition. The occurrence of three cases of intussusception in the one family could result from some environmental factor, but this would seem to be unlikely. According to definition, a condition is considered to be hereditary if there is organic resemblance based on descent. Since no information is available regarding the occurence of intussusception in the parental generation, the condition cannot be said to be hereditary. A trait is said to be congenital if it is present at or before birth. The present patients apparently did not exhibit any evidence of their common tendency at birth but may have possessed some common characteristics at that time, which, in each case, led to the development of their common condition. A study of a consecutive series of families in each of which a malformed child was born has revealed that the parents of a child with a congenital malformation are more likely to give rise to another malformed child than would be expected by chance. In a consecutive series of families in which two or more malformed children were born, the defect in the second child was found to be the same as that in the first malformed sibling, in approximately one chance out of two. This is a high frequency when one considers the great variety of congenital defects to which man is heir.

TUBERCULOSIS OF KIDNEY

To the Editor:—*A patient suffers from tuberculosis of the kidney. One kidney was removed, and the patient is under treatment with dihydrostreptomycin and* p-*aminosalicylic acid, six tablets four times a day. The patient vomits often. Is there anything to prevent the patient from vomiting? Is it advisable to change from* p-*aminosalicylic acid to an isoniazid product?*

Ralph L. Icken, M.D., Astoria, N. Y.

Answer.—It seems clear that the patient is sensitive to the quantity of *p*-aminosalicylic acid being given. There are several ways this problem can be met. Try to correct the problem with as little disturbance as possible to the treatment of the patient. It is suggested that the sodium *p*-aminosalicylic acid be changed to calcium *p*-aminosalicylic acid and half dosage be given for a few days. Then if no ill effects result, to continue on to the full dosage. This will correct most problems of burning, nausea, and vomiting. If not, the treatment should be stopped for 10 days and then started again with small doses, 100 mg. a day, gradually increasing the amount until the patient can tolerate the full dosage. It is sometimes effective to use the effervescent salt instead of the simple salt, or effervescent salts may be given with the calcium salt if an effervescent product is not available. One of these methods should correct the condition. The potassium salt has been recommended by Molthan and his associates (*Am. Rev. Tuberc.* 71:220, 1955). There is no special advantage in using the potassium salt, except to desensitize and to restrict sodium intake. Neither will it be necessary to use intravenous medication. In a recent report in the 14th Chemotherapy Conference of the Veterans Administration, the Army, and the Navy, Lattimore has shown that he obtains better results in genitourinary tuberculosis when all three drugs are used, than when only two are used. It would be good practice, therefore, to add isoniazid, 300 mg. a day, to the schedule already in use.

LUPINE BEANS

To the Editor:—*I have a 65-year-old woman patient with moderate diabetes whose fasting blood sugar level runs between 150 and 200 mg. per 100 cc. without insulin. Recently on a trip to Italy she ate lupine beans. A blood sugar level taken two months after her return was 90 mg. per 100 cc. It has never been close to this level in 10 years. What is the action of these beans?*

M.D., New York.

Answer.—There are nearly 7,000 species of legumes. They were mentioned 2,000 years B. C. Lupine beans resemble lima beans, of which the average composition, dried according to "Chemical Composition of American Food Materials" (Bulletin 28, U. S. Department of Agriculture, 1906) is water 10.4%, protein 18.1%, fat 1.5%, carbohydrate 65.9%, and ash 4.2%. The edible portion of fresh lima beans contains water 8.5%, protein 7.1%, fat 0.7%, carbohydrate 22.0%, and ash 1.7%, but as purchased refuse 55%, water 30.8%, protein 3.2%, fat 0.3%, total carbohydrate 9.9%, and ash 0.8%. Mrs. Julia F. Morton, vice-director of Morton Collectanea of the University of Miami, writes as follows: "The seeds of several species of Lupinus are still used as food by the poorer classes of the Mediterranean region after special measures are taken to remove toxic principles which apparently vary with species, locality and season. However, in modern literature, lupines are dealt with primarily as hazards to grazing animals, though certain strains are valued as forage." Lupines have been responsible for many losses in domestic animals, especially sheep, in Europe and America. Eighty species of lupines are recorded from the plains and mountains of America. Obviously it would be unjustifiable to attribute a fasting blood sugar value on a single day after a trip to Italy to what was eaten or done on the trip even though more data were available, such as a knowledge of the quantity and quality of the diet, the amount of exercise taken, and the weight of the patient before and after the trip. An Italian patient reports that lupine beans are often eaten with wine as pretzels are taken with beer. At first the beans are soaked for two days in cold water, and then they are boiled and kept for two weeks. The outer layer of the bean is removed with the fingers, and the bean is eaten. Most likely on the patient's trip to Italy the beans were substituted for a dessert that would have been richer in carbohydrates and of which she would probably have consumed more.

BILATERAL CHARCOT JOINTS

To the Editor:—*A man, aged 54, has bilateral "Charcot joints" of the hips. He was given 8 million units of penicillin in 1947, developing a severe allergy to same. In 1950 the right hip joint enlarged and was explored, removing about a quart of cartilaginous "mice." He was then given two years of continuous treatment with alternating courses of arsenic and bismuth. In 1954 the left joint began to show a similar degenerative process. Consultation resulted in a difference of opinion regarding further treatment. He is Wassermann-fast, and the spinal fluid is negative. 1. Does this patient need more antisyphilis therapy? 2. Does a prosthesis of the head of the femur usually give good results in this condition?*

M.D., Texas.

Answer.—The neuropathic arthropathy (Charcot joint) of tabes dorsalis is not beneficially influenced by any treatment, whether with metal chemotherapy or antibiotics. Nothing will be gained by additional such treatment given to the patient with bilateral Charcot hips. Operative procedures for the relief of this condition in the hip are usually totally unsatisfactory. In the case of Charcot degeneration of such a stable joint as the hip (in contrast to the much less stable joints in the feet, ankles, and knees), a trial of androgenic therapy with testosterone propionate is thoroughly justified. This form of treatment has of course been used for other osseous lesions, such as metastatic cancer and ununited fractures, and has also been used (results unpublished) in a small series of patients, perhaps five or six in number, with Charcot hips. The administration of testosterone in large parenteral doses (100 mg. daily to a total of 3,000 to 4,000 mg. in a course) has, in certain patients with Charcot hips, resulted in increased blood calcium and the deposition of new bone in and around the disintegrating joint. This new bone deposition has created what is, in essence, "a false joint" and has enabled a few patients to get around with braces rather than with crutches. If this form of treatment is undertaken, it should, of course, be with the usual clinical and blood chemical controls of massive androgenic therapy. There is a clinical impression on the part of a number of observers (not verified by actual biostatistical data) that in patients with progressive Charcot joints further breakdown of the joint may be stopped by fever therapy with induced tertian malaria. The most that can be expected from this however, if indeed it occurs, is an arrest of the process without any improvement. In the long run, the management of all Charcot joints is an orthopedic problem.

DIMINISHED SPERM COUNT

To the Editor:—*A young couple each aged 25 consulted me because of infertility. The husband was found to have a sperm count of 200,000 and 400,000 per cubic centimeter on two occasions each preceded by a period of abstinence of 14 days. His history disclosed mumps orchitis at age 12, and physical examination revealed marked atrophy of one testis and less than normal size in the other. Is there any worthwhile treatment for this markedly diminished sperm count? Can the "rebound phenomenon" be applied in this case?*

James F. Kennedy, M.D., Alliance, Neb.

Answer.—The morphology of the spermatozoa should first be studied. If there is found to be a high proportion of abnormal forms, no benefit can be expected from treatment. Attempts to evoke a "rebound phenomenon" in cases of oligospermia are a gamble. The immediate effect of large doses of androgens is to depress still further the already poor spermatogenesis. In some men the sperm count subsequently rises above pretreatment levels. In others a "rebound" fails to occur, and the patient is then left worse off than he was originally. This consultant would hesitate to advise this method in the present case. By centrifuging semen deficient in number of spermatozoa it is possible to obtain material with a comparatively high concentration. This may be used for artificial insemination with a syringe or, alternatively, may be placed in a cervical cap and left in contact with the external os for several hours.

OCCUPATIONAL DERMATITIS

To the Editor:—*I have treated several patients with an occupational dermatitis. They have been working with metals, and several of them have stated that when they come in contact with magnesium, their hands seem to break out. I have tried to find some references to this metal and its effect in the literature, but so far I have not been able to find any.*

Albert Rubin, M.D., Hartford, Conn.

Answer.—This query fails to state the nature of the work involving metal handling, such as metal founding, metal machining, or metal polishing. Although other metals are mentioned as a group, none is named save magnesium. If magnesium founding was the work in question, dermatitis readily might arise not from the magnesium itself (apart from heat burns) but from the ammonium borofluoride or other fluorides commonly introduced into the mold. If machining operations constituted the work, then under some circumstances any occupational dermatitis might derive from cutting oils or other cutting compounds. If the other metals mentioned but not named included nickel, then nickel dermatitis as an allergic manifestation could arise. The characteristic action from occupational employment of metallic magnesium leads to the appearance of subcutaneous gas tumors from implanted magnesium slivers. Otherwise, neither on a contact basis nor allergy is a dermatitis expectable from the manipulation of metallic magnesium.

THROMBOANGIITIS OBLITERANS

To the Editor:—*The Sphygmo-oscillometer reading on one leg of a patient was nearly zero while on the other leg it was almost five. A consultant diagnosed thromboangiitis obliterans and did a sympathectomy about a month ago. The affected leg shows only a little increase in the sphygmo-oscillometer reading but the patient feels that it is better. Would the oscillometric reading ordinarily parallel the actual improvement, or is it normally delayed in its indication?*

O. C. Amstutz, M.D., Irvine, Ky.

Answer.—The oscillometer is a relatively insensitive instrument. Considerable clinical improvement may take place with relatively little change in oscillometer readings. Improvement in collateral circulation would be reflected in higher skin surface temperatures rather than greater oscillometer readings.

TAMPONS

To the Editor:—*Please comment on the use of tampons and sanitary napkins in relation to carcinoma of the cervix. Are there any statistics on this subject?* *M.D., Virginia.*

Answer.—There is no proof to show that the use of tampons or sanitary napkins leads to carcinoma of the cervix. Brand (*Brit. M. J.* **1**:24, 1952) studied 100 women who used vaginal tampons during 3 to 10 successive menstrual periods. Smears and cultures taken before and after each period showed no appreciable change in the bacterial flora of the vagina. Healing of erosions was not adversely affected, and there were no signs of local irritation or inflammation. Although there is no evidence that vaginal tampons are prejudicial to health, a retained tampon may damage the vagina or cervix. Patients should be warned to remove the soiled tampon before inserting a fresh one. Bowles (*Proc. Staff Meet., Straub Clin.* 18:48, 1952) reports three instances of cervicitis, vaginitis, and a foul vaginal discharge due to forgotten vaginal tampons.

MAGNESIUM RODS IN HOT WATER HEATING UNITS

To the Editor.—*Our warm water heating unit is made of galvanized iron. To prevent rusting and corrosion it is equipped with a so-called magnesium rod. Is the water used from such a unit harmful for human consumption?*

M.D., New York.

Answer.—It is a frequent practice to include a magnesium rod inside hot water heating units. This is done to provide selective electrolysis, the magnesium being much more readily attacked than the galvanized or other coating on the iron. Slowly, this magnesium rod disintegrates with a continuous liberation of small quantities of hydrogen gas and magnesium ions into the ambient water. These additives to the water are harmless. The additional amount of magnesium is likely to provide a total less than naturally found in many hundreds of water supplies. So far as known nothing detrimental attends the use of these magnesium rods.

SUPPRESSION OF OVULATION

To the Editor:—*Would the use of an androgen hormone parenterally, when used for the control of dysuria during premenstrual tension, have any adverse effect on ovulation?*

M.D., Illinois.

Answer.—Small amounts of androgens will not interfere with ovulation; however, larger amounts may suppress ovulation, and the resultant menstrual flow will be anovulatory in character. No residual damage will result, for the cessation of therapy will be followed by a prompt recurrence of normal ovarian function. A basal body temperature graph kept by the patient will demonstrate whether the dose of androgens administered has suppressed ovulation in any given cycle.

In the present study, 100 patients with malignant lymphoma, consisting of 65 cases of Hodgkin's disease, 18 of lymphosarcoma, 5 of reticulum cell sarcoma, and 12 of unclassified lymphoblastoma, were treated with either nitrogen mustard or triethylene melamine. One hundred eighty-nine courses of the drugs were given. Nitrogen mustard was given to 68 patients intravenously in doses of 0.1 mg. per kilogram of body weight per day for four consecutive days. Some of the patients were hospitalized, but most were treated as outpatients. This necessitated occasional modifications of the dosage schedule.

COMPLICATIONS

Three types of complications were observed: (1) local tissue reaction following injection of nitrogen mustard, (2) gastrointestinal distress, and (3) hematopoietic depression. The local reactions consisted of cellulitis or phlebitis and were seen in eight patients. They occurred when nitrogen mustard was given without dilution and were eliminated when the nitrogen mustard solution was injected into tubing carrying a freely flowing intravenous infusion of isotonic sodium chloride solution. Gastrointestinal distress, in the form of epigastric burning, nausea, or vomiting, occurred in 52 patients. These symptoms occurred mainly after administration of nitrogen mustard. One patient stated that the treatment was worse than the disease, but most were disturbed only minimally and were relieved by sedation. Various other measures failed to influence the reaction. Recently chlorpromazine [10-(γ-dimethylaminopropyl)-2-chlorophenothiazine hydrochloride] has been useful in the control of gastrointestinal upsets. Patients receiving triethylene melamine were given aluminum hydroxide gel orally before ingesting the tablets, and, while epigastric distress was a common complaint, it never was necessary to discontinue treatment because of this. Hematopoietic depression occurred in 54 of the 100 patients treated. The patients were divided into three groups on the basis of the hematological manifestations: a first of 46 patients, in which peripheral leukocyte or platelet depression was absent; a second of 32 patients, in which the leukocyte count was depressed below 5,000 white blood cells per cubic millimeter; and a third, of 22 patients, in which the leukocyte count dropped below 3,000 or the platelet count below 100,000 cells per cubic millimeter. Eight of the 22 patients with severe depressions experienced alarming complications, and of these died. Detailed bone marrow studies were obtained on three of the patients and revealed marked atrophy of the normal marrow elements.

The incidence of complications did not appear to be related to the specific disease process. Five of the serious depressions occurred in the 65 cases of Hodgkin's disease (8%), two in the 18 cases of lymphosarcoma (11%), and one in the 12 cases of unclassified lymphoblastoma (8%). Previous treatment with irradiation or chemicals was the factor most directly related to the occurrence of peripheral blood depression (see table). A second factor of importance was the general condition of the patient. The bone marrows of those patients who were debilitated or had widespread disease were affected most by the medication.

Sixty-eight patients were treated with nitrogen mustard. Twenty-four of them had had no previous treatment, and 13 of the 24 (54%) showed no significant blood change. Ten of the 24 patients (42%) developed a moderate white blood cell depression (count below 5,000 per cubic millimeter), and only one patient's white blood cell count fell below 3,000 cells per cubic millimeter (4%). This patient was in a debilitated state when his treatment was begun. Forty-four patients had had previous treatment, with irradiation, nitrogen mustard, or triethylene melamine, and 22 (50%) showed no significant blood change. Thirteen (29%) developed a moderate bone marrow depression, while nine (21%) developed serious depressions. Of these nine patients, two died and another had a serious hemorrhage but recovered. The others recovered without complications.

A total of 44 patients were treated with triethylene melamine. Nine had had no previous treatment. Only one, a patient with widespread disease, developed a serious white blood cell depression (11%). Thirty-five patients had had previous irradiation or nitrogen mustard therapy. Seventeen (49%) showed no significant blood change. Moderate peripheral blood depression occurred in 7 (20%), while serious depression was seen in 11 patients (31%). In the latter group, three died, two had severe hemorrhage, and six made an uneventful recovery. Twelve patients had bone marrow depression after triethylene melamine therapy. Initial courses of 1 mg. per day for 21 days did not cause any significant blood change in any of 23 patients. Second courses of 1 mg. per day caused serious bone marrow depressions in four of six patients (66%). Five milligrams per day, during either initial or second courses, caused serious depression in 8 of 22 patients (36%). This occurred after an average of 38 mg. of the drug had been given and seemed more related to the total dose given than to the spacing of the doses within the schedules followed. In all eight alarming hematopoietic depressions were encountered. One massive hemorrhage and two deaths followed nitrogen mustard therapy. Two massive hemorrhages and three deaths followed triethylene melamine therapy.

Effects on Leukocyte Count of Nitrogen Mustard and Triethylene Melamine Therapy

Drug	No. of Patients Treated	Count Above 5,000		Count Below 5,000 and Above 3,000		Count Below 3,000	
		No.	%	No.	%	No.	%
Nitrogen mustard							
No previous therapy	24	13	54	10	42	1	4
Previous therapy	44	22	50	13	29	9	21
Triethylene melamine							
No previous therapy	9	6	66	2	23	1	11
Previous therapy	35	17	49	7	20	11	31

In our experience nitrogen mustard and triethylene melamine proved to be effective drugs. Eighty-one per cent of the patients treated improved, 14% showed no improvement, and in the remaining 5% the effect could not be evaluated. In the patients who died as a result of the marked hematopoietic depression and came to autopsy, active malignant lymphoma still was present.

REPORT OF CASES

CASE 1.—A 40-year-old white male had Hodgkin's disease manifested by cervical and mediastinal adenopathy. He was treated extensively with roentgen rays and received two courses of nitrogen mustard. Eighteen months after the second course of nitrogen mustard and nine months after the last roentgen ray treatment, he was given a third course of nitrogen mustard, 0.1 mg. per kilogram of body weight daily for four days. His pretreatment blood cell count showed 5,700 white blood cells and 250,000 platelets per cubic millimeter. Forty days after the beginning of this therapy, while in another city, he had massive melena and required repeated transfusions. He recovered from this episode but continued on a downhill course and died three months later.

CASE 2.—A 29-year-old white male had Hodgkin's disease manifested by widespread adenopathy, hepatomegaly, weight loss, chills, and fever. He was treated with nitrogen mustard and irradiation. Although seriously ill, he was given 0.1 mg. per kilogram of body weight of nitrogen mustard daily for three consecutive days. Ten days after the beginning of this therapy, the leukocytes decreased from 3,150 to 1,400 per cubic millimeter and the platelets from 270,000 to an estimated "very few." Despite administration of a total of 75 mg. of corticotropin, he died 20 days after the beginning of the last treatment.

CASE 3.—A 20-year-old white female had Hodgkin's disease manifested by enlarged cervical and mediastinal lymph nodes. She was treated with two courses of irradiation and one course of nitrogen mustard. Six months later, even though her condition was precarious, a second course of nitrogen mustard, 0.04 mg. per kilogram of body weight per day for four days, was given. Three weeks later she developed a leukopenia (1,300 cells per cubic millimeter). She then was given 40 mg. of corticotropin daily for 19 days and made clinical improvement. At this time, her white blood cell count was 2,000 cells per cubic millimeter and she again was given nitrogen mustard, 0.1 mg. per kilogram of body weight daily for four days. Ten days after this treatment was begun, her white blood cell count had dropped to 100 cells per cubic millimeter and practically no platelets could be found. She died three days later, after massive hemorrhages.

CASE 4.—A 30-year-old white female had Hodgkin's disease manifested by enlarged cervical, axillary, and mediastinal lymph nodes. She received two courses of nitrogen mustard. This was followed with roentgen rays over a two year period. Pulmonary infiltration developed, and she was given a total of 35 mg. of triethylene melamine, 5 mg. every three days. Nineteen days after treatment was begun, her white blood cell count had dropped from 17,700 to 2,900 cells per cubic millimeter and the platelets from 540,000 to 370,000 per cubic millimeter. She was hospitalized elsewhere and died 53 days after the beginning of the therapy.

CASE 5.—A 30-year-old white female had Hodgkin's disease manifested as a left upper pulmonary lobe tumor, which was diagnosed by exploratory thoracotomy and biopsy. She was given a tumor dose of 3,000 r of roentgen rays followed by 35 mg. of triethylene melamine, 5 mg. every three days. Twenty days after the start of therapy with triethylene melamine, her white blood cell count had dropped from 6,700 to 1,800 and the platelet count from 290,000 to 120,000 per cubic millimeter. She developed massive gastrointestinal hemorrhages and epistaxis, which required transfusion of 7 liters. She recovered from this episode after six weeks of hospitalization.

CASE 6.—A 38-year-old white male had lymphosarcoma manifested by generalized lymph node enlargement and weight loss. He had been given irradiation on three occasions. He was given a total of 35 mg. of triethylene melamine, 5 mg. every three days. Twenty-six days after this treatment was begun, the leukocytes decreased from 35,000 to 3,000 and the platelets from 270,000 to 80,000 cells per cubic millimeter. He was hospitalized two days later because of the pancytopenia, which required 16 blood transfusions. Three months later the white blood cell count was 9,950.

CASE 7.—A 41-year-old white female with reticulum cell sarcoma of the tonsil and neck was first treated with irradiation. Fourteen years later, a large nonresectable abdominal mass showed a similar histological picture. She was given a cours of 21 mg. of triethylene melamine. At the close of this treatment her white blood cell count was 4,600 and her platelet coun 400,000 cells per cubic millimeter. The abdominal mass did no diminish in size, and, two weeks later, she was started on furthe triethylene melamine therapy in 1 mg. daily doses. After 10 mg had been taken, she developed nausea, petechial hemorrhages melena, and hemoptysis. She died 23 days after the beginnin of the final therapy from a cerebral hemorrhage.

CASE 8.—A 43-year-old white male had lymphoblastom manifested by enlarged cervical lymph nodes. He was treate with roentgen rays and showed a satisfactory response. Eigh months later, he received 35 mg. of triethylene melamine i three weeks' time. Twenty-six days after treatment began, h white blood cell count had fallen to 2,250 and the platelet cour to 17,600 cells per cubic millimeter. By 40 days after treatmer began, his count had risen to 8,300 white blood cells and 81,00 platelets. Because of advancing disease, triethylene melami therapy was resumed at a dosage of 5 mg. twice a week. Aft he had received 35 mg. in this second course, his white bloo cell count fell to 1,850 and his platelet count to a very few ce per cubic millimeter. He died 75 days after the beginning initial therapy of agranulocytosis, which was confirmed autopsy.

COMMENT

Nitrogen mustard and triethylene melamine ha been found to be effective and convenient tools in t treatment of the malignant lymphomas. However, the drugs may cause severe and uncontrollable depressi of the hematopoietic system. We encountered 54 i stances of significant depression in the cellular elemen of the blood in the 100 patients to whom 189 courses either nitrogen mustard or triethylene melamine we given. The toxicity of these drugs varied inversely wi the condition of the patient and the intensity of previo treatment. The patients with early disease, almost wit out exception, tolerated initial courses of either drug, the amounts we gave, without appreciable drops in t blood cell count. However, patients with widespre disease or who received prior therapy with roentg rays, nitrogen mustard, or triethylene melamine did r tolerate the drugs well. They exhibited alarming dro in the number of blood elements, both circulating a marrow, after receiving minimal doses of the drugs. is imperative that the hematological status of all patie be known before treatment is instituted and that freque checks be made as treatment progresses. Hematopoie depression may be observed 10 to 51 days after the b ginning of treatment, and careful observation shou continue for at least this period. Once a serious leuk penia or thrombocytopenia has occurred the only effe tive treatment is repeated transfusion. The hematolo cal picture was not altered significantly by either cor sone or corticotropin. Eighty-one per cent of our p tients improved under treatment; however, residual m lignant lymphoma was present in all of the patients w came to autopsy.

SUMMARY

When nitrogen mustard (Mustargen) was admini tered daily in a dosage of 0.1 mg. per kilogram of bo weight for four days to 24 patients who had not receiv previous treatment, serious bone marrow depression w seen in only one instance (4%), and this occurre in a patient with widespread disease. However, whe nitrogen mustard was given in the same dosage to 4 patients who had previous treatment with radiatio nitrogen mustard, or triethylene melamine (TEM nine instances (20%) of serious bone marrow depression occurred. Similarly, when triethylene melamine was given to nine patients who had no previous therapy, only one instance (11%) of serious bone marrow depression occurred. When triethylene melamine was given to 35 patients who had previous treatment, 11 instances (31%) of thrombocytopenia and/or leukopenia occurred. Of the 100 patients treated, 8 had alarming bone marrow depressions, and 5 of these died.

BOWEL FUNCTION AFTER COLECTOMY FOR CANCER, POLYPS, AND DIVERTICULITIS

Richard C. Lillehei, M.D.
and
Owen H. Wangensteen, M.D., Minneapolis

Subtotal or total colectomy for certain colic lesions was described by one of us in 1943.[1] This procedure has been applied with increasing frequency to lesions of the left half of the colon in succeeding years. On the surgical service of one of us (O. H. W.) since 1946, subtotal or total colectomy has come to be the surgical procedure of election in cases of cancers of the left colon as well as for multiple polyps of the colon. Moreover, in many instances of diverticulitis, a total or subtotal colectomy has been done in which multiple diverticula extended into the upper reaches of the descending colon or well into the transverse colon. Undetected polyps have been uncovered by these wider excisions, and, in one instance of diverticulitis, an occult cancer was found in the cecum when the operatively removed specimen was opened. In fact, total or subtotal colectomy has come to be the operative procedure of choice whenever colectomy has been undertaken for any lesion of the colon distal to the hepatic flexure. Only the necessity of excising a segment of ileum in cecal cancers to insure removal of the potential lymphatic drainage area has made caution necessary in extending the primary excision in cancers of the cecum to include the greater portion of the left colon. As the experience of this study suggests, however, it is essentially the extent of excision of ileum that determines whether diarrhea will follow; excision of the colon per se apparently is not attended by diarrhea extending long beyond the period of hospital stay. In fact, it is more usual for patients to leave the hospital after total colectomy having few or no imposed dietary strictures and reporting having not more than two stools a day.

It is the purpose of this paper to report the results of this study and, in particular, to report upon the influence of total or near total colectomy upon the bowel habits of patients. The study is primarily concerned with the presence of occult or undetected polyps or carcinomas, which prompts our interests in extension of excision of the colon over the more conventional hemicolectomy or segmental resection. That such lesions may be overlooked in the latter type of operation is becoming increasingly evident. Moreover, it is also obvious that when such occult lesions are left behind, subsequent surgery is necessitated and the cure rate for cancer is diminished. Most students of colic cancer now believe that the majority of adenocarcinomas of the colon develop from preexisting polyps.

It has been frequently stated that approximately 75% of polyps and cancers of the colon and rectum are within reach of the sigmoidoscope. It has been the ambition of many to extend this range. Theoretically, it should be feasible to visualize the colon preoperatively as far as the splenic flexure. Hedin,[2] in 1939, devised such an instrument, but it has not come into common use. Many surgeons employ a proctoscope at the operating table to inspect the remaining colon after a subtotal resection; unfortunately, this procedure is handicapped too frequently by poor visualization. This is especially true in the right half of the colon, which is more difficult to prepare preoperatively. Also, there is the ever-present danger of fecal contamination of the operative field. As the most reliable alternative, we have come to employ routinely more extensive excision of the colon as a preferable solution when dealing with polyps or carcinoma of the colon. This experience forms the basis for this study.

Polyps of the colon and rectum were once considered a rarity. Allingham,[3] in 1888, commented on the relative infrequency of polyps in his experience in 4,000 proctoscopies. Recently, more accurate observations on the true incidence of polyps in the adult population have been made. In a recent report [4] from the Cancer Detection Center of the University of Minnesota, 17% of 3,364 patients examined over a three year period were found to have one or more polyps of the colon and rectum. All the patients in this entire group were between the ages of 45 and 64 years. Obviously, age is an item to be considered when the incidence of rectal or colic

polyps is discussed. Multiple carcinomas of the colon occurring simultaneously or successively in time have long been recognized by surgeons interested in this problem and constitute a definite problem in surgical treatment of malignancies of the colon. Excluding the condition of disseminated or familial polyposis, which is not being considered specifically in this paper, Bargen and Rankin [5] found two or more carcinomas in 4.6% of

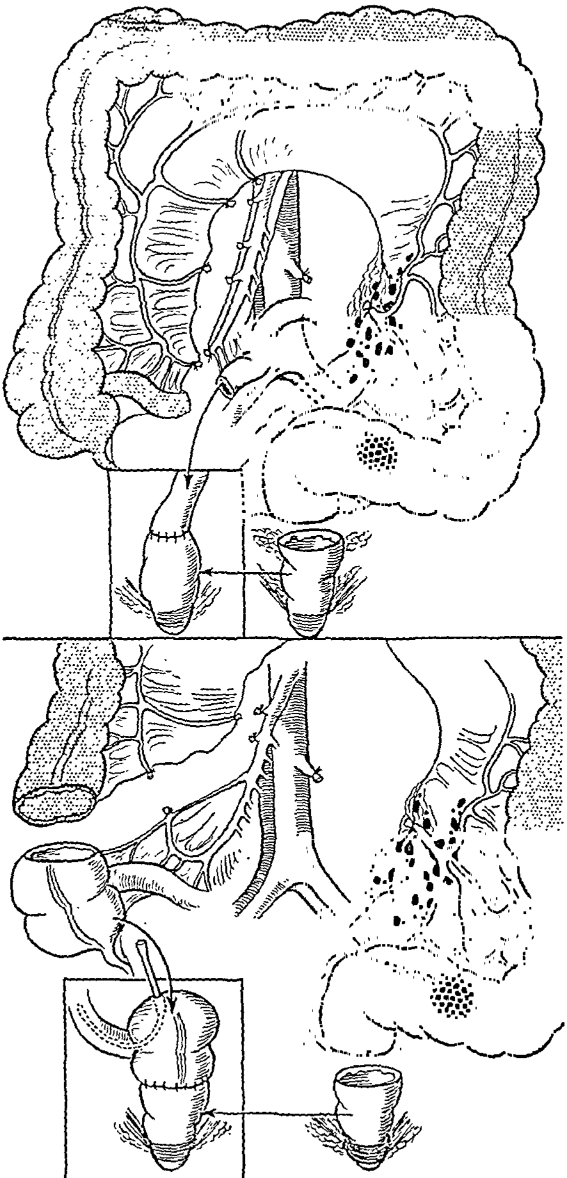

Fig. 1.—Extent of operation in total or subtotal colectomy for cancer of colon beyond hepatic flexure.

344 cases of carcinoma of the large intestine. Many similar reports that document this evidence are to be found in the literature. In 1942, Mayo and Schlicke [6] reported 131 autopsies performed within three weeks after operations for carcinoma of the colon and rectum. Forty-nine of the 131 cases (37.4%) had polyps in the remaining colon. There was a second carcinoma present in the residual colon in seven cases (5.3%).

STUDY GROUP AND METHOD

All patients included in the present group had a total or near total colic resection including, in many instances, resection of varying amounts of terminal ileum. The period of the study extended from Jan. 1, 1946, to April 1, 1954. Patients who had a total or near total colic resection for lesions other than polyps or carcinoma also were included in the group. This was done for the sake of completeness as well as for evaluation of postoperative function of the bowel after total or subtotal colectomy under a variety of conditions. The only patients excluded from this study were those in whom a palliative resection was undertaken or in whom subtotal or total colectomy was undertaken for ulcerative colitis. Both of these conditions pose special problems in the evaluation of postoperative function of the bowel after colectomy; however, the hospital mortality rate for palliative

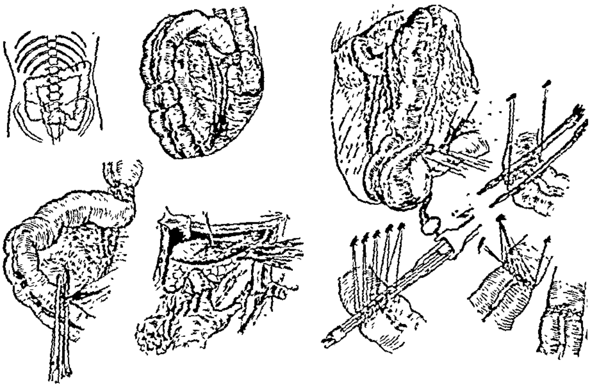

Fig. 2.—Technique of total colectomy for cancer or other lesions the colon. The anastomosis is made by the closed method, employing single row of fine silk sutures.

resections or for ulcerative colitis did not exceed that the cases reported herein. In some cases the cecum a 2 or 3 cm. of ascending colon were preserved in an tempt to evaluate the importance of the ileocecal val in the prevention of postoperative diarrhea. The col resection was done in one stage; a closed end-to-en single row anastomosis was made in all instances, method that has been employed in this clinic for almo 15 years. The majority of the patients had no speci preparation of the colon prior to surgery other than th administration of an enema. An examination of the lite ature [7] suggests that the open anastomosis is being use more frequently again in the United States.

In the early years covered by this study the decisio to perform a total or near total resection including vary ing amounts of terminal ileum was usually made at th operating table. This decision was based on one or bot of the following reasons: (1) the presence of multipl lesions involving several segments of the colon, such a multiple carcinomas, polyps, or diverticula, with diver ticulitis scattered throughout the colon or spread to th colon from malignancies of adjacent organs; (2) th finding of an unsuspected polyp or a second cancer i

the excised segment of colon near the proximal line of resection in lesions of the descending colon or near the distal line of resection in lesions of the right colon or transverse colon. The excised segment of colon was brought directly to the pathologist, who would inspect the opened specimen and report his findings to the surgeon, who was also shown the opened cylinder of colon. The surgeon then decided whether further resection was required. The second finding enumerated above, namely, finding of polyps near a line of resection, was the most frequent indication for enlarging the extent of the colectomy. In the more recent years covered by the period of this study, and instructed by our accumulative experience, one of us (O. H. W.) has come to feel that, in the standard-risk patient, primary total or subtotal colectomy is the operation of choice in all colic cancers beyond the hepatic flexure of the colon, inasmuch as no ileum need be excised. In carcinomas of the right colon, however, it is always necessary to remove a sizable segment of the terminal ileum in order to insure adequate removal of the lymph drainage area —a consideration that has made us more reluctant to accept total or subtotal colectomy as a primary operation for cancer of the cecum or ascending colon. In a few patients, a segmental colectomy or hemicolectomy had been done previously at this or other hospitals for a carcinoma and/or polyps of the colon. These patients required reoperation and removal of the remaining colon because of polyps or a new primary carcinoma in the remaining colon. Table 1 indicates the primary diagnosis in each of the 73 patients undergoing total or subtotal colectomy. In patients with carcinoma the lesions were located at 10 cm. or more from the anus. In those patients whose lesions necessitate abdominoperineal excision of the rectum, we do not as yet advise ileostomy but continue to make the colostomy in the descending colon or in the transverse colon, as suggested by State.[8] Twenty of the cancers were in the left colon, 14 were in the transverse colon, and 9 were in the right colon. Many of the cases of carcinoma were accompanied by polyps in close proximity. Of the 12 patients with polyps, only 2 could be classed as having polyposis, although there was no familial history of polyposis in either patient. There were 10 cases of diverticulitis, and the remaining 8 cases were of a miscellaneous nature.

Function of the bowel after surgery was classed as good, fair, or poor. Good function was interpreted to mean a return to normal or near normal bowel habits, with one to three bowel movements each day and stools of fairly normal consistency. The term fair function was employed to suggest that the patient had four to six movements a day and that the stools usually were of a loose consistency. Poor function included those patients who had more than six bowel movements per day; the stools of these patients were usually watery. Those patients in whom function of the bowel fell between the criteria outlined above were placed in the lower rather than in the higher classification. All but two patients have been followed since surgery. The interval of observation varies therefore from eight months for the most recent cases to eight years for the earlier cases in the series. Almost all the patients were interviewed personally; the remainder were contacted by questionnaire. The results of interviews, the questionnaire, and previous notations on the clinical records following postoperative outpatient visits to the clinic were integrated to obtain the necessary information.

FINDINGS

Table 2 contains an analysis of 60 of the 73 cases as to level of anastomosis, length of terminal ileum removed with the colon, and resulting function of the bowel. The level of the anastomosis was noted at the time of surgery, and the proctologist usually indicated the observed location of the anastomosis in subsequent proctoscopic examinations undertaken when the patient revisited the clinic at six-month intervals. The rectum is considered to be 13 cm., on the average, in length. The term iliac colon is employed in this clinic in accordance with conventional anatomic nomenclature to designate that portion of the colon beginning just above the rectum (third sacral vertebra) that becomes the sigmoid colon at the level of the sacral promontory. The iliac colon has no mesentery and is usually 6 to 8 cm. in length. All anastomoses included in this report were made either with inclusion of the rectum or the iliac colon.

TABLE 1.—*Diagnosis in Seventy-Three Patients Undergoing Colectomy*

Condition	Patients, No.
Carcinoma	43
Left half of colon	20
Transverse colon	14
Right half of colon	9
Polyps	12
One or more	10
Polyposis	2
Diverticulitis	10
Miscellaneous	8
Carcinoma of the ovary	3
Carcinoma of the stomach	2
Retroperitoneal fibrosarcoma	1
Pseudomyxoma peritonei	1
Mesenteric thrombosis	1

TABLE 2.—*Results of Anastomosis Between Ileum and Iliac Colon or Rectum in Sixty Patients Undergoing Total or Subtotal Colectomy*

		Good		Fair		Poor			
Level from Anus, Cm.	Total No. Patients	No.	Amount Resected, Cm.	No.	Amount Resected, Cm.	No.	Amount Resected, Cm.	Lost	Deaths
17-21	27	16	Less than 30	5	76 70 38 36 12*	3	62 51 40	1	2
13-16	19	14	Less than 30	3	76 38 34	1	42	1	..
7-12	14	9	Less than 30	1	15†	2	70 67	..	2

* This 82-year-old patient is classed as having only a fair result because, although she has only 2 to 3 bowel movements a day, she complains of incontinence.

† This patient has had some dysfunction of the colon despite resection of less than 30 cm. of terminal ileum. She has 4 to 5 bowel movements a day.

The patients were almost equally divided as to sex, and the average age was 60 years. Anastomosis between ileum and colon, at the level of 17 to 21 cm. from the anus, was done in 27 patients. In 16 of these patients the resulting function of the bowel was good; in 5 it was fair; and in 3 the present function of the bowel is poor. In the group with only fair function, 76, 70, 38, 36, and 12 cm. of terminal ileum, respectively, was resected along with the colon. The patient in whom only 12 cm. of terminal ileum was removed with the colon is an 82-year-old woman who complains now of some incontinence, although she has only two to three bowel movements each day. For this reason she was classed as having only a fair result. The three patients having poor function had 62 cm., 51 cm., and 40 cm. of terminal ileum, respectively, resected with the colon. One patient cannot be traced, and there were two postoperative deaths in this group. One of these occurred on the 10th day and was due to peritonitis. The other death occurred on the 49th postoperative day and was complicated by the occurrence of a persistent biliary fistula resulting from a coincidental complementary cholecystectomy; persistent severe diarrhea and a poor cardiac status from an antecedent coronary thrombosis were the important contributing factors in the lethal issue. At the postmortem examination the patient was found to have an unrecognized stone in the common bile duct. Operative intervention for closure of the complete biliary fistula had been contemplated and might have saved the patient. Anastomosis of ileum and iliac colon between 13 and 16 cm. from the anus was done in 19 patients. Postoperative function of the bowel has been good in 14 patients, fair in 3, and poor in 1. One patient was lost to follow-up. Seventy-six, 38, and 34 cm. of terminal ileum, respectively, were removed with the colon in each of the three patients classed as having a fair result. One patient who had 42 cm. of terminal ileum resected with the colon has had a persisting diarrhea. Fourteen ileoproctostomies between 7 and 12 cm. from the anus were done. Nine patients have had a good result. One patient has had a fair result, although only 15 cm. of terminal ileum was removed with the colon. This patient is one of two patients who has had some dysfunction of the bowel, despite resection of less than 30 cm. of terminal ileum with the colon. Two patients showing poor results had 70 and 67 cm. of terminal ileum, respectively, removed with the colon. There were two deaths. One patient died postoperatively of clinical hepatic failure on the eighth postoperative day. No postmortem examination was permitted. The other patient died on the seventh postoperative day of suppurative pancreatitis and congestive heart failure. The suture line was completely intact.

TABLE 3.—*Incidence of Occult Polyps and Cancer*

Condition	Cases No.	Cases %
Polyps	55	100.0
Occult	21	38.0
Cancer	43	100.0
Unsuspected simultaneous (occult) cancer remote from primary cancer	3*	7.0
Successive colic cancers	5	11.6
Total	8	18.6

---

* An additional unsuspected cancer was found in the cecum of one of the patients undergoing colectomy for diverticulitis.

Colectomy with preservation of the ileocecal valve and sphincter was done in 13 patients. This procedure was done only for cases of carcinoma of the left colon or for polyps or diverticulitis. Function of the bowel after anastomosis of the cecum to the iliac colon or rectum, as low as 7 cm. from the anus, was good in all cases. Anastomosis between 17 and 21 cm. from the anus was done in four patients. In one of these it was necessary to resect coincidentally 90 cm. of jejunum; however, no adverse effect on postoperative function of the bowel was seen. In six patients anastomosis between 13 and 16 cm. from the anus was performed, and in three patients the level from the anus was between 7 and 12 cm. There were no postoperative deaths.

In the patients in this series, there were four postoperative deaths, the ages of the patients being 72, 65, 62, and 77 years. The over-all hospital mortality rate was 5.5%. Autopsies were performed on three of the four patients who died. The causes of death were peritonitis, hepatic failure, biliary fistula with common bile duct stone, and acute suppurative pancreatitis and congestive heart failure. All patients (with only two exceptions) having three or less bowel movements per day had either no terminal ileum removed or had less than 30 cm. removed with the colon. Most patients usually had some diarrhea in the hospital, but their length of hospital stay did not seem to exceed the time spent in this hospital by those having the more conventional type of colic resections. The over-all average hospital stay for the group was 14 postoperative days, many patients going home several days earlier. Diarrhea had usually disappeared before the patient left the hospital, and most of the patients established their permanent pattern of bowel function within two to three months after surgery. A few patients continued to improve up to one year, and in no instance did function of the bowel become wors with the passing of time.

Hidden Lesions.—A significant finding, justifying th procedure described herein, has been the finding of un suspected lesions, polyps, and carcinomas, which hav been found in a large number of these patients (table 3 A large number of polyps were found that were n recognized preoperatively when the usual diagnostic pr cedures were used. No polyp was counted as havin been detected by this method of extended excision the colon unless the lesion was found in a segment colon that would not have been removed with employ ment of the conventional segmental colectomy or hem colectomy. Such polyps, located beyond the reach the more conservative procedure of hemicolectom were found in 22 patients. In 21 patients the polyps wer associated with a carcinoma and/or polyps in anothe portion of the colon. The remaining case concerned u detected polyps and an occult cancer encountered durin colectomy performed for extensive diverticulitis. In thi group of 73 patients there were 55 patients who ha polyps or a carcinoma of the colon or both. Thus, 2 of 55 patients (38%) had occult polyps that would hav been missed without the more extensive colectomy. Thi figure agrees closely with the findings of Mayo an Schlicke[6] in their autopsy studies on polyps that re mained in the colon after colic resection for carcinoma

Sixteen of these 21 patients had the unsuspected polyps in the right or the transverse colon, with the larger number in the right colon. The remaining five patients had unsuspected polyps in the left colon, more than 25 cm. from the anus. In these patients the diagnostic procedures employed preoperatively included barium enema in 11 cases and barium enema together with an air contrast study in 11 cases. The average size of the polyps was 1 cm. in diameter, with the range varying between 0.5 to 3.5 cm.

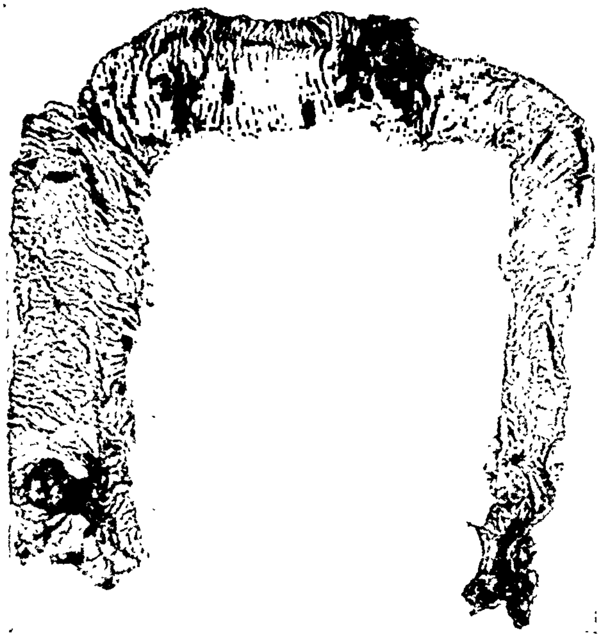

Fig. 3.—Excised colon showing two definite cancers, one in the splenic flexure, the other in the ascending colon. There were also multiple small benign polyps throughout the colon, and the lymph nodes were involved in the area of the cancer in the splenic flexure.

A second carcinoma was discovered in 3 of the 43 patients with carcinoma of the colon (7%). In all three, the second carcinoma was in the cecum or in the ascending colon and accompanied a carcinoma of the left colon, for which operation was primarily undertaken. In none of the three were the second carcinomas detected preoperatively. In addition, in one patient whose case is cited above, operation was undertaken for diverticulitis, and unsuspected polyps were found in the left colon and a small carcinoma of the cecum was observed in the right colon by the pathologist after excision of the colon was done. Neither the polyps nor the carcinoma were recognized in preoperative x-ray studies. In the group of 43 patients with carcinoma of the colon, there were 5 patients who developed a new primary carcinoma of the colon within a period of from six months to 17 years after a previous colic resection. Thus, 8 of 43 patients (18.6%) in whom resection was done for a colic cancer had either simultaneously or successively two independent carcinomas of the colon.

REPORT OF CASES

Case 1.—A 70-year-old man was operated on early in 1954 for a carcinoma of the splenic flexure (fig. 3). A barium enema revealed no other lesions. At surgery, a hemicolectomy including most of the transverse colon was done. On opening the specimen, there were two polyps, 0.5 cm., near the proximal line of resection. For this reason the remainder of the right colon and 10 cm. of terminal ileum were excised also. A lesion could be definitely felt through the cecal wall. In the cecum was a 3 cm. polypoid lesion that proved to be a carcinoma on microscopic section and one additional 0.5 cm. polyp. The patient made an uneventful recovery, and, when last seen six months after his operation, he was having two bowel movements each day.

Case 2.—A 71-year-old man was first seen at this hospital in 1933, at which time a hemicolectomy on the right was performed for an adenocarcinoma of the cecum. Ten centimeters of terminal ileum was excised with the colon. The patient returned at irregular intervals for barium enemas, and in 1949 a filling defect was seen in the transverse colon. A decision to temporize with this finding was made, and he was not seen again until one year later. At that time repetition of the barium enema showed the filling defect to have enlarged, and he was again operated on. A carcinoma and two small polyps were found in the transverse colon. The remaining colon and 9 cm. of terminal ileum were excised, and an ileoproctostomy was done at 12 cm. from the anus. The patient has continued to be able to work, and function of the bowel is normal.

Case 3.—A 51-year-old man was operated on at a clinic in 1951, at which time a segmental resection was done for an adenocarcinoma of the descending colon. In 1952 he was again operated upon at the same clinic, at which time a segment of the transverse colon, together with the splenic flexure of the colon, was excised for polyps. Two of the polyps were reported as manifesting "grade 1" malignant changes. He was first seen here in 1953, at which time he complained of gas pains and an intermittent colic fistula. A barium enema showed an area of partial obstruction near the splenic flexure. He was reoperated on, and the remaining colon, together with 3 cm. of terminal ileum, was excised. On opening the excised specimen, the site of obstruction was found to be at the previous anastomosis. In addition, a segment of transverse colon, 34 cm. in length, was found to be completely studded with small polyps (fig. 4). The ascending colon and lower iliac colon were free of polyps. An anastomosis was made between the ileum and the rectum. At

Fig. 4.—Colon, showing an extensive polypoid lesion, which is entirely benign. Two prior segmental colic resections had been done one year previously.

the present time, 18 months after surgery, he has one to two bowel movements daily and is completely happy with the present situation.

CASE 4.—In 1950 a 62-year-old man was hospitalized for the excision of a polyp in the descending colon. There was also evidence of an extensive diverticulitis of the colon. The distal third of the transverse colon, the entire descending colon, and the greater portion of the sigmoid colon were excised. The polyp in the descending colon was found, together with smaller polyps at either end of the specimen. An additional length of colon was then excised on the proximal side, reaching well into the ascending colon. A polyp was found near the proximal site, and the segment was excised, together with 2 or 3 cm. of the ileum. On the distal side the excision was extended to the level of the sacral promontory. There were no additional polyps in this latter segment. The pathological diagnosis was multiple polyps and diverticula throughout the colon and adenocarcinoma of the cecum. The patient has remained well, and there has been no diarrhea.

CASE 5.—On Jan. 5, 1954, a 34-year-old man was admitted to the University Hospital because of polyposis of the colon. He gave a history of bleeding from the rectum since October, 1953. At that time, he underwent proctoscopic examination. Fulguration of several polyps was carried out to a distance of 20 to 22 cm. from the anal orifice. After this procedure the colon became perforated, and the patient was operated upon for closure of the site of perforation. He subsequently was sent here for excision of the polyps in the colon. Several visible polyps in the rectum within the reach of the proctoscope were destroyed by fulguration, except for one large polyp at 16 cm. from the anus. It was felt that this polyp was too large for fulguration. An air contrast study showed several polyps throughout the colon, particularly in the descending colon. A total colectomy was done, excising all the colon save for a small cuff of the cecum at the ileocecal juncture. It was estimated that not more than 8 square centimeters of cecal mucosa remained. This area was spared so that the ileocecal valve would be left and diarrhea avoided. The appendix was excised, and an end-to-end anastomosis was made between the midrectum, 8 cm. from the anus, and the cecum by the closed technique. After the appendix was excised, a small catheter was pushed through the ileocecal valve into the ileum at the site of appendectomy. The anastomosis was made outside the peritoneal cavity. The specimen showed 13 polyps. There was a cluster of polyps in the pelvic colon; however, there was a free area of polyps extending to within 7 cm. of the distal line of resection and to within 2.5 cm. of the proximal line. The polyps were all benign on microscopic examination. The pathological diagnosis was polyposis. The patient did well and was dismissed from the hospital on Jan. 18, 1954, 12 days after the operation. There has been no diarrhea at any time since operation. He has been examined proctoscopically at four month intervals in the outpatient clinic. There are no residual polyps either in the rectum or in the small cuff of remaining cecal mucosa.

The history of the patient in case 5 is particularly interesting. Leaving the ileocecal valve appears to protect against the occurrence of diarrhea. When the ileocecal valve and sphincter are spared ordinarily, a segment of 4 to 5 cm. in length containing a full thickness of the cecal wall remains. In the instance of this patient a cuff of cecum just long enough to spare the ileocecal valve was left. No polyps apparently were left in the cecum. Moreover, Dr. W. C. Bernstein, proctologist to the University Hospital, and one of us (O. H. W.) have a few patients with multiple polyps of the colon and rectum under observation in whom total colectomy has been done, leaving the rectal segment. Dr. Bernstein, has been able to keep the condition under control, and no rectal cancers have been observed in this small series of patients.

COMMENT

If all or nearly all of the colon can be removed in thos patients who are predisposed to the future developmen of carcinomas of the colon without crippling them unnecessarily with diarrhea and without pyramiding th operative mortality, the procedure should prove to hav definite value. Any remaining segment of colon is the within reach of the proctoscope and is available for read annual proctoscopic inspection. In the group under discussion here, the entire colon, and in some instances a much as 30 cm. of terminal ileum, was excised with n greater morbidity than that associated with a less extensive colectomy. Only two patients who had less than 3 cm. of terminal ileum removed with the colon have ha difficulties with postoperative function of the bowel A study of hemicolectomies on the right done in thi hospital reveals similar findings. In those patients i whom terminal ileum of lengths greater than 30 to 4 cm. was removed along with the right colon, difficultie in function of the bowel often resulted. This circumstance would appear to suggest that the main functio of the left colon is one of storage. Fortunately, it i usually not necessary to remove more than 30 cm. o terminal ileum, even for a carcinoma of the cecum. Thi study of the results of colectomy in lesions of the righ colon has made us more alert to the importance of nc removing too much terminal ileum with such lesions i diarrhea is to be avoided. Whenever the enlargement o the lymph nodes in the ileocecal mesentery in ceca cancers suggests the necessity of sacrificing more tha 30 cm. of terminal ileum with its mesentery, we hav not hesitated to do so.

The terminal ileum and the right colon constitut the "water wringer" [1] of the intestine. The precise limit of terminal ileum to which water reabsorption is confine are not known. Sharply defined limits are difficult to establish because of the adaptive process of the ileum fo water reabsorption. When more than 30 cm. of termina ileum is excised with the colon, there is considerable individual variation in the degree of postoperative dysfunction of the bowel. A few patients in whom 70 cm. o more of terminal ileum was resected along with th colon have had less diarrhea than a few patients i whom only 40 to 50 cm. of terminal ileum was remove with the colon.

With regard to the amount of rectum to be retained the preservation of the full thickness of the wall o the terminal rectum of a segment as short as 5 cm. wil insure complete and normal continence. Several anastomoses as low as 5 cm. from the anus have been made in this clinic during the past decade, with preservation of normal continence. Whether the anastomosis was made in the upper rectum or at a lesser distance from the anus seems to have made little difference in subsequent function of the bowel. Obviously, it is a simpler operation to effect an anastomosis to the iliac colon than to the rectum. In the aged, continence may be impaired despite preservation of the lower rectal segment with its sphincters. This circumstance was observed in an 82-year-old woman in this group.

Although the number of cases is small, retaining the ileocecal valve has proved to be an important asset in insuring the preservation of normal function of the bowel. Kremen[9] and his associates made the important observation in dogs that the preservation of the ileocecal valve with 2 or 3 cm. of terminal ileum protects against diarrhea even when the distal half of the small intestine is removed. Wherever feasible, it would appear to be wise therefore in colic resections to preserve the ileocecal valve.

Mortality.—The hospital mortality rate in the group (5.5%) is not excessive when compared with that for colectomies reported from this hospital in other years. Since April 1, 1954, subtotal or total colectomy has been done in 6 additional cases with no hospital mortality, therefore making the over-all mortality for the 79 cases 5%. In 61 consecutive cases of colic resection over a 2 year interval reported from this clinic in 1943,[1] there was a hospital mortality of 1.6%. These resections, carried out by the closed method of anastomosis, done at a time when neither intestinal antibiotics nor penicillin were available, represent the best achievement of this clinic on the score of mortality in the surgical management of colic lesions. In that group of 61 patients, there were 7 subtotal excisions of the colon in which the ileum of the cecum was anastomosed to the iliac colon; in this small group there were no deaths. In a larger series reported in 1945,[10] there were 6 hospital deaths among a total of 78 cases, a mortality of 7.6%. Combining the two reported series in 1943 and 1945 gave an over-all hospital mortality rate of 5%.

Special or Earlier Adaptations of Total or Subtotal Colectomy.—Total or near total colectomy has not been used frequently in the past for the treatment of malignancies and polyps of the colon, although Lane[11] in 1914 recommended a one-stage colectomy with ileoproctostomy 40 years ago. The mortality rate for the procedure he used was under 10%, a truly remarkable accomplishment for that time. Lane employed colectomy for treating chronic constipation, which he believed was the basis for a large number of the ills of the body. While colectomy had little effect upon the primary disease of his patients, it did cure their constipation. Indeed, several patients in the present study were more appreciative of the relief of their constipation than of the removal of a cancer. In very severe constipation that has constituted a major problem for the patient, resistant to conventional modes of therapy, hemicolectomy on the right that is combined with excision of approximately 50 cm. of terminal ileum has occasionally been done in this clinic, with results pleasing to the patient and surgeon as well.

Colectomy with ileoproctostomy has been employed by surgeons for several years in treating familial polyposis. Mayo and Wakefield,[12] Hoxworth and Slaughter,[13] and others have reported small numbers of cases of polyposis treated in this manner with good results. One of the earlier applications of subtotal colectomy in this clinic[14] was for colic obstruction in both the right and the left colon. Baronofsky[15] advocated primary subtotal colectomy in treating certain cases of obstruction of the large intestine to overcome the difficulties of anastomosing distended intestine of dubious viability. Such a procedure avoids the preliminary colostomy and its attendant prolongation of hospitalization. By this procedure Baronofsky noted too the presence of unsuspected polyps in remote areas of the colon. The experience of this clinic[16] suggests, however, that, in the presence of great intestinal distention, a preliminary decompressive operation is to be preferred to primary colectomy in the management of acute obstruction of the left colon.

Other Devices to Improve Accomplishment in Colic Cancer.—No effort has been made in this study to compare five year survival rates with those reported by others, inasmuch as the number of patients available for a 5 year follow-up study would be rather small. It is evident that in addition to excising more potential malignant lesions, a greater area of mesentery with its regional lymph-node-bearing area is excised as well. Recurrences due to the seeding of cancer cells in the colic lumen from handling the primary lesion at surgery are minimized. The importance of the mechanism of seeding as a cause of recurrent carcinoma of the colon has recently been emphasized by Cole[17] and his associates. A word would appear to be in order concerning the inability of our present methods of investigation to demonstrate certain lesions in the colon. It is not always possible to get an accurate roentgen examination of the more proximal colon. The presence of obstructing lesions in the left colon, the poor preparation of the right colon, and the necessity of examining increasing numbers of patients without sufficient time or personnel thwart an accurate examination. Clinicians and surgeons, therefore, need to recognize their responsibility in the early detection of these polyps and small cancers in the proximal reaches of the colon. It is not a task to be left solely to the roentgenologist. The inability of the roentgenologist to visualize the interior of the more proximal colon with the same degree of accuracy as the lower left colon probably explains in part the frequency with which

polyps were found in the right and proximal transverse colon in this study. It seems likely too, on the basis of these findings, that polyps of the right colon occur more frequently than has been previously appreciated.

"Second-Look" Procedure. — Employment of the "second-look" operation in patients with colic cancer who are found to have cancer in the regional lymph nodes is beginning to prove its worth.[18] At intervals of six months, long before the expiration of the "silent period," another operation is carried out in patients with cancer in the lymph nodes, at which time the whole operative field is carefully and thoroughly surveyed. Lymph-node-bearing tissue in areas adjacent to the normal lymph drainage sites of the initial lesion is removed. A few regional lymph nodes next to the aorta and vena cava are removed, and a punctilious search is made for evidence of any residual cancer. Any suspicious tissue is removed and is submitted to careful histological study. It is usual to remove and label 20 to 30 pieces of tissue for paraffin fixation and study in such second-look procedures. Such reentries are made at successive intervals of six months, until a final exploration is negative. In one patient, a "sixth look" was necessary before the patient was found to be free of cancer. In the recently reported evaluation of the second-look procedure in patients with colic cancer, there were 33 patients who were found to have cancerous lymph nodes at the primary operation and consequently were subjected to a second-look procedure. Of these, 17 were found to be free of cancer; 15 have remained well, and 2 have died of causes unrelated to cancer. Of the 16 patients who still had residual cancer at the first second-look operation, 5 (31.2%) no longer have cancer as a result of successive second looks. Obviously, all of these five patients, in time, would have succumbed to their cancers. It is plain that it is necessary to resist being too optimistic over this accomplishment. And certainly, it will take additional years to determine exactly what the second-look procedure has to offer in colic malignancy. The present record suggests definitely, however, that it has a contribution to make.

SUMMARY AND CONCLUSIONS

When total or subtotal colectomy is done for polyps or carcinoma of the colon, a number of concealed lesions are uncovered, remote from the site of the primary lesion that compelled the operation. In this study, 38% of patients with an initial diagnosis of carcinoma of the colon and/or polyps were found to have additional polyps in a portion of the colon that was believed to be uninvolved preoperatively. These polyps would not have been removed if the conventional hemicolectomy on the right or the usual segmental colectomy on the left had been employed. In three patients, an unsuspected carcinoma was found in the removed specimen of the colon. In this group of patients, 18.6% developed, either simultaneously or successively in time, a second carcinoma of the colon. An unsuspected cancer of the cecum was found in a fourth patient, who underwent colectomy for diverticulitis. If not more than 30 cm. of terminal ileum is excised with the colon, function of the bowel postoperatively is usually quite normal. The hospital mortality rate for total or subtotal colectomy compares favorably with that for less extensive colectomies. In this series of 73 total or subtotal colectomies, the hospital mortality was 5.5%. If no ileum is excised, persistent diarrhea following total or subtotal colectomy is practically nonexistent. Preservation of the ileocecal valve assures normal function of the bowel attending subtotal or near total colectomy. Cecorectal anastomoses are performed by choice when the diameter of the distal component of the anastomosis is large. The remaining ring of cecal mucosa can be inspected through the proctoscope.

This experience would appear to indicate that total or subtotal colectomy is an acceptable operation for all lesions of the colon in which no ileum, or a very short segment thereof, needs to be removed. In fact, the frequency with which findings important to the patient are uncovered suggests that total or subtotal colectomy should become, under favorable circumstances, the operation of choice for cancers of the colon beyond the hepatic flexure. And, for cancers of the cecum and ascending colon in which less that 20 cm. of ileum is sacrificed, the surgeon may extend the excision of colon to the iliac colon or rectum without undue concern over leaving the patient with persistent diarrhea. This extension of the conventional confines of partial colectomy should, if accepted by surgeons, make an additional impress upon improving the present accomplishment in colic cancer. Finally, it would appear that "second-look" operations are indicated in patients with colic cancer who are found, at the primary operation, to have involvement of the regional lymph nodes.

Aneurysm of Middle Cerebral Artery.—The detection of aneurysm involving the middle cerebral artery on either side is extremely difficult prior to rupture. In this respect the aneurysms of the middle cerebral artery differ greatly from those found elsewhere in the circle of Willis. In aneurysms arising in relation to most of the large vessels characteristic syndromes have been elucidated, so that the diagnosis may be determined on clinical grounds alone, often without benefit of arteriography. On the contrary, the symptoms referable to the aneurysms of the middle cerebral artery are indeterminate and nonspecific. . . . In the [author's] series . . . the only symptom of significance prior to rupture consisted of headache of a nonspecific character. . . . There was nothing in the constellation of symptoms prior to rupture which could be utilized to point to the possibility of aneurysm. It is possible that the combination of headache, focal seizures, aphasia, and transient weakness might give rise to the consideration of middle cerebral artery aneurysm as a diagnostic possibility, but the symptoms can hardly be regarded as specific. . . . After rupture it is not always possible to be altogether certain whether the symptoms result from aneurysm, hemorrhage into a tumor, or cerebral hemorrhage of hypertensive origin. The difficulties arise in regard to the two last possibilities because of the presence of choked disc in some instances, and the differentiation can be made only on the basis of further studies.—K. Frankel, M.D., and B. J. Alpers, M.D., The Clinical Syndrome of Aneurysm of the Middle Cerebral Artery, *A. M. A. Archives of Neurology and Psychiatry*, July, 1955.

HEMORRHAGIC DISORDER FOLLOWING MASSIVE WHOLE BLOOD TRANSFUSIONS

Julius R. Krevans, M.D.
and
Dudley P. Jackson, M.D., Baltimore

With the increasing use of whole blood transfusions, a variety of untoward reactions have been recognized. One such complication is the development of a hemorrhagic diathesis. This has been observed after hemolytic transfusion reactions [1] and after the infusion of blood that has been contaminated with bacteria.[2] More recently, abnormal bleeding has been observed after transfusion of unusually large amounts of compatible blood.[3] Recently a patient was observed to develop severe abnormal bleeding and profound thrombocytopenia after the rapid infusion of 20,500 ml. of whole blood during a surgical procedure. This observation prompted a study of the effects of blood transfusions on the platelets and the blood coagulation mechanism.

MATERIAL AND METHODS

During the period from July, 1954, through January, 1955, 32 patients were studied. These patients were hospitalized on the surgical, medical, or pediatric services of the Johns Hopkins Hospital. With one exception, donor blood was collected by gravity through plastic tubing into plastic bags, each containing 75 ml. of acid-citrate-dextrose solution. The needles used with these donor sets were of laminar-flow design and were coated to be hemorepellent. All blood was stored at 4 C for a period of less than 21 days. The blood was administered through disposable plastic recipient sets. When rapid infusion of the blood was required, external pressure was applied to the plastic bags. One patient (case 2) received blood that had been collected in standard, glass vacuum bottles with plastic tubing. Rapid infusion of the blood was accomplished in this case by the use of a rotary, mechanical pump. All cross matchings were performed with cells suspended in saline solution and in bovine albumin. In addition, cross matchings by the indirect Coombs technique were performed when the patient had a history of previous transfusions or pregnancies.

Platelets were counted by the phase-contrast technique of Brecher and Cronkite [4] in which 1% ammonium oxalate is used as a diluent. The counts were performed, in duplicate, from pipettes filled at the bedside with venous or capillary blood. The normal range is 150,000 to 300,000 per cubic millimeter. This technique has the advantage of being more accurate than other procedures used for counting platelets. In addition, simultaneously prepared blood smears stained with Wright's stain were examined. Hemostatic function studies were performed with techniques as previously recorded.[5]

RESULTS

Thirty-two patients who received one or more whole blood transfusions were studied. Five of these patients were newborn infants on whom exchange transfusions were performed for hemolytic disease of fetus and newborn, and 27 were adults who received transfusions for a variety of clinical disorders. The ages of the 27 adult patients ranged from 38 to 86 years. All but four patients had pretransfusion platelet counts or pretransfusion blood smears available for estimation of platelet levels. There was no history of thrombocytopenia or abnormal bleeding in any of these patients.

Adult Patients Receiving More Than 5,000 Ml. of Whole Blood.—Fourteen adult patients received from 5,500 ml. to 20,500 ml. of whole blood within a 48 hour period (table 1). In addition, five of these received dextran in amounts not exceeding 1,000 ml. In all of these patients, the need for massive whole blood transfusions arose during a surgical procedure. After the transfusions, all developed significant thrombocytopenia and 11 displayed one or more of the following clinical evidences of abnormal bleeding: cutaneous petechiae (fig. 1), ecchymoses, excessive bleeding from the operative site, bleeding from the mucous membranes, gastrointestinal hemorrhage, and hematuria. Only two of these patients survived (cases 5 and 9). All 14 had some degree of shock, and in 8 severe protracted shock was noted and ultimately was resistant to further transfusions and to the administration of arterenol (nor-epinephrine). Other studies of hemostatic function were performed in seven cases; the results are summarized in table 2. The whole blood clotting time was prolonged in only one instance (case 1). Significant hypoprothrombinemia was found in three patients (cases 4, 8, 12). The patient in case 4 had cirrhosis with moderate hypoprothrombinemia before surgery and transfusions. Case 8 will be recorded in more detail below. The patient in case 12 had a carcinoma of the stomach with an abscess extending into the pancreas. After surgery this patient developed chemical evidence of obstructive jaundice and

hypoprothrombinemia. Moderate hypofibrinogenemia was encountered only in the patient is case 8. Summaries of several illustrative cases follow.

CASE 1.—A 50-year-old white male was admitted because of thrombotic occlusion of the abdominal aorta. On July 7, 1954, the thrombotic segment of the aorta was excised and a frozen dried homograft was inserted. During the nine hour operative procedure, the patient received 17,500 ml. of whole blood. On the first postoperative day the patient developed a hemorrhagic diathesis manifested by hematuria and gastrointestinal bleeding and he was given 3,000 ml. of whole blood. During the second postoperative day he had marked hematuria, rectal bleeding, bloody mucus in the trachea, and large amounts of blood in his aspirated gastric contents. On this day the patient received 1,000 ml. of whole blood and continuous arterenol infusions. On the third postoperative day the abnormal bleeding continued and, because of the possibility of mesenteric thrombosis, an exploratory laparotomy was performed. At operation there was a large amount of clotted blood in the retroperitoneal area. A few hemorrhages in the transverse colon were noted, and no thrombosis was found. He received an additional 500 ml. of blood. On the fourth postoperative day, severe abnormal bleeding continued. The patient received 500 ml. of whole blood, and administration of arterenol was continued. Laboratory studies at this time revealed: hematocrit 52%, icteric index 50, white blood cell count 7,000 per cubic millimeter, platelet count 5,200 per cubic millimeter, whole blood clotting time 58 minutes, prothrombin time >65% of normal, clot retraction markedly impaired, rate of conversion of prothrombin to thrombin (prothrombin consumption) impaired, plasma fibrinogen 450 mg. per 100 cc., and clot lysis time normal; an assay for circulating anticoagulants was negative. On the fifth postoperative day the abnormal bleeding continued and arterenol therapy was required for severe hypotension. He received an additional 500 ml. of whole blood, and his platelet count was 6,000 per cubic millimeter. He had a generalized convulsion, lapsed into coma, and died on the sixth postoperative day.

TABLE 1.—*Platelet Levels After Transfusions of from 5,500 to 20,500 Milliliters of Whole Blood*

Case No.	Age (Yr.), Race, and Sex	Diagnosis	Pre-Transfusion, Platelets/ Cu. Mm.	Total Blood Given, Ml.*	Post-Transfusion, Platelets/ Cu. Mm.†	Outcome	Remarks
1	50 W M	Excision of abdominal aneurysm	......	20,500	5,200	Died	Excessive bleeding from wound; rectal bleeding; hematuria; oligu protracted shock
2	53 W F	Bleeding duodenal ulcer; transfixion of ulcer and pyloroplasty	Normal on smear	17,000	56,000	Died	History of porphyria; no abdomi bleeding
3	70 W M	Nephrectomy	......	16,000	46,000	Died	Excessive bleeding from wound; petechiae; protracted shock
4	42 W M	Cholecystectomy; liver biopsy; Laennec's cirrhosis	163,000	15,500	18,000	Died	Excessive bleeding from wound; subcutaneous bleeding; hematuria protracted shock; diffuse bleedin when reexplored
5	43 N M	Multiple gunshot wounds of abdomen	Normal on smear	15,500 (1,000 ml. dextran)	22,000	Survived	Hematuria; protracted shock
6	45 W M	Actinomycosis; right upper lobectomy	Normal on smear	12,500	39,000	Died	Excessive bleeding from wound; petechiae; diffuse bleeding when reexplored
7	53 W F	Alcoholic gastritis with bleeding; subtotal gastrectomy	Low normal on smear	10,500 (225 ml. dextran)	51,000	Died	Excessive bleeding from wound; petechiae; continued gastrointest bleeding
8	64 W M	Excision of abdominal aneurysm	Normal on smear	9,500 (500 ml. dextran)	47,000	Died	Rupture of aortic graft; reoperat diffuse bleeding during second op tion; protracted shock
9	54 N M	Excision of thoracic aneurysm	194,000	9,500	34,000	Survived	Hematuria; protracted shock
10	61 W F	Carcinoma of breast; erosion of subclavian artery	......	9,000 (500 ml. dextran)	64,000	Died	Petechiae
11	69 N M	Carcinoma of pancreas; 2-stage Whipple procedure	Normal on smear	8,000	58,000	Died	Excessive bleeding from wound; gastrointestinal bleeding
12	55 N M	Carcinoma of stomach; subtotal gastrectomy; splenectomy	Normal on smear	7,500 (850 ml dextran)	93,000	Died	No abnormal bleeding; protracte shock
13	86 N M	Excision of thoracic aneurysm	152,000	7,000	38,000	Died	No abnormal bleeding; protracte shock
14	75 W F	Bleeding gastric ulcers; subtotal gastrectomy	Normal on smear	5,500	44,000	Died	Diffuse bleeding during surgery; ecchymoses; hematuria; protract shock

* Total blood given within a 48 hour period. † Lowest post-transfusion platelet count.

CASE 6.—A 45-year-old white male was shown to have actino mycosis of the upper lobe of the right lung. Laboratory resul on Nov. 17, 1954, were: hematocrit 41.6%, white blood ce count 8,700 per cubic millimeter, and platelets normal on staine blood smear. After one month of therapy with intramuscularl given penicillin, a lobectomy was performed. During this thre hour procedure the patient received 2,500 ml. of whole bloo and there was difficulty controlling the bleeding from the ve vascular pleural surfaces. After operation he continued to blee from the operative site, and an additional 4,000 ml. of bloo was administered during this day. Laboratory studies at th time revealed: hematocrit 39%, icteric index 13, platelet cou 79,000 per cubic millimeter, whole blood clotting time minutes, prothrombin time >50% of normal, clot retracti slightly impaired, and plasma fibrinogen 226 mg. per 100 c On the first postoperative day he continued to bleed from t operative site. After administration of an additional 6,000 m of blood and 3 gm. of calcium gluconate, the laboratory stud were repeated and the results were: hematocrit 42.7%, icte index 8, platelet count 39,000 per cubic millimeter, and plas fibrinogen 260 mg. per 100 cc. Because of continued bleed from the chest, an exploratory thoracotomy was performed. operation multiple bleeding points were noted in the pleura a cutaneous purpura appeared on the neck and shoulders. Duri this two hour procedure, efforts were directed at effecting lo hemostasis, and the patient received 2,500 ml. of whole blo and 1.53 gm. of fibrinogen intravenously. Immediately followi the operation, laboratory examinations revealed: plasma fibr ogen 299 mg. per 100 cc., carbon dioxide combining pow 33.1 mEq. per liter, and serum calcium 10.5 mg. per 100 On the third postoperative day bleeding from the operative s diminished, but cutaneous petechiae continued to appear. T patient received an additional 500 ml. of whole blood. Labo tory studies at this time revealed: hematocrit 42%, platelet cou 50,000 per cubic millimeter, and CO_2 combining power 36 mEq. per liter. During the day the patient developed progressive respiratory difficulty and died.

CASE 8.—A 64-year-old white male was admitted for resection of an abdominal aortic aneurysm. The admission laboratory findings were: hematocrit 40.1%, white blood cell count 8,800 per cubic millimeter, platelets normal on smear, and serologic tests for syphilis negative; an aortogram revealed an aneurysm of the abdominal aorta. On July 15, 1954, the aneurysm was excised and a nylon graft was inserted. During this three hour procedure the patient received 2,000 ml. of whole blood and no abnormal bleeding was noted. On the first postoperative day the patient suddenly developed profound shock and evidences of intraperitoneal hemorrhage. At exploratory laparotomy, the ruptured graft was replaced. This operative procedure lasted four hours, and the patient received 11,000 ml. of whole blood and 1,000 ml. of dextran. During this operation, and after the patient had received 7,500 ml. of whole blood and 500 ml. of dextran, diffuse oozing was noted from all cut surfaces. Hemostatic function studies at this time revealed: platelet count 47,000 per cubic millimeter, whole blood clotting time 29 minutes, prothrombin time 50% of normal (the prothrombin time was not shortened by the addition of barium sulfate-adsorbed plasma from a normal individual), and plasma fibrinogen was 91 mg. per 100 cc. One hour after completion of this surgical procedure, and after the infusion of 11,000 ml. of whole blood and 1,000 ml. of dextran, the plasma fibrinogen level was 171 mg. per 100 cc. The patient never regained consciousness and expired one hour later.

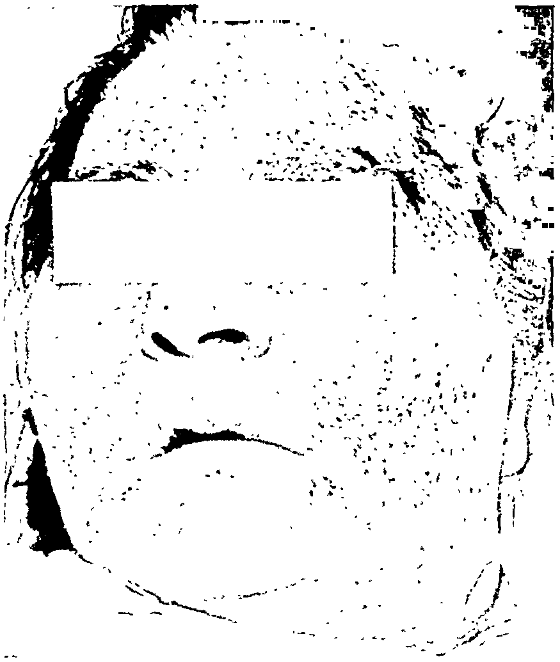

Fig. 1.—Appearance of petechiae in patient in case 10 on the day after surgical procedure. During operation the patient was in Trendelenburg position. In the preceding 24 hours the patient had received 9,000 ml. of whole blood. Platelet count at the time the photograph was made was 64,000 per cubic millimeter.

CASE 9.—A 54-year-old Negro male was admitted for excision of an abdominal aneurysm. Laboratory studies revealed: hematocrit 39%, white blood cell count 8,400 per cubic millimeter, platelet count 194,000 per cubic millimeter, and serologic tests for syphilis positive; an aortogram revealed an aneurysm of the abdominal aorta. On Aug. 16, 1954, the aneurysm was excised and a frozen dried homograft inserted. Platelet counts were performed twice during this six hour operative procedure. During the second hour of operation, after the patient had received 1,000 ml. of whole blood, the platelet count was 143,000 per cubic millimeter. During the fourth hour of the operation, after the patient had received an additional 2,500 ml. of blood, the platelet count was 34,000 per cubic millimeter. Because of a friable aortic segment, considerable bleeding was encountered at surgery, but no diffuse bleeding was noted. One hour after surgery, and after a total of 9,500 ml. of whole blood had been administered, the platelet count was 41,000 per cubic millimeter. During the first postoperative day there was slight bleeding from the operative site and some bleeding around the urinary catheter was noted, but there was no hematuria. The platelet count was 50,000 per cubic millimeter. The patient received 1,000 ml. of whole blood. On the second postoperative day an additional 500 ml. of whole blood was administered. No further bleeding was noted, and the platelet count was 60,000 per cubic millimeter. On the third postoperative day the platelet count was 52,000 per cubic millimeter. No additional transfusions were administered. On the 4th postoperative day the platelet count was 67,000 per cubic millimeter; on the 7th, 147,000 per cubic millimeter; and on the 10th, 593,000 per cubic millimeter. Four weeks after surgery the platelet count was 518,000 per cubic millimeter, and the patient was discharged two weeks later. Five months after surgery the platelet count was 395,000 per cubic millimeter. This patient's course is summarized in figure 2.

TABLE 2.—*Hemostatic Function Studies in Patients Receiving Multiple Whole Blood Transfusions*

Case No	Amount of Blood Received, Ml.	Platelets/ Cu. Mm.	Clotting Time, Min.*	Prothrombin Time, % of Normal	Fibrinogen, Mg./ 100 Ml.	Other
1	20,500	5,200	58	>65	450	Clot lysis time normal; clot retraction impaired; prothrombin consumption impaired; anticoagulant assay negative
3	16,000 18,500	46 000 106,000	33 ..	>65 >50	251 296	Clot retraction impaired
4	7,500 15,500	77,000 18,500	34 ..	45 >50	... 179	....
6	6,500 12,500 13,000 and 1.53 gm. fibrinogen I.V.	79,000 39,000	25	>65	225 260 300	Clot retraction slightly impaired
8	9,500 13,000	47 000	29 ..	50	91 171	....
10	9,000	83,000	28	>65	430	Clot lysis time normal; clot retraction slightly impaired
12	7,500	93,000	15	30	178	Clot retraction slightly impaired; bilirubin, total 23.6 mg. per 100 cc., direct 19.6 mg.

Normal range 15 to 35 min.

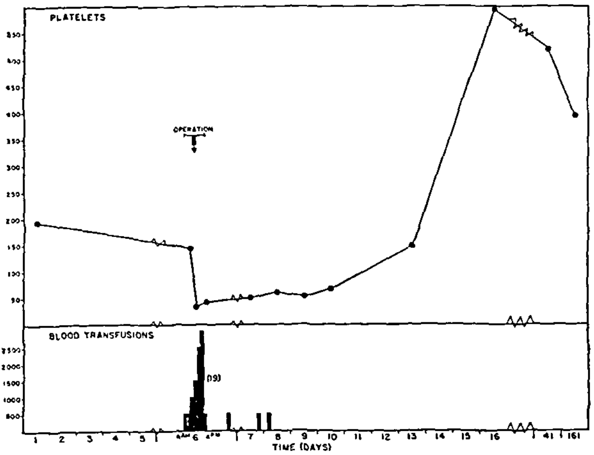

Fig. 2.—Summary of course of patient in whom aneurysmectomy was done (case 9).

Adult Patients Receiving Less Than 5,000 Ml. of Whole Blood.—Thirteen adult patients received from 500 ml. to 4,500 ml. of whole blood within a 48 hour period (table 3). None of these patients showed any evidence of a hemorrhagic diathesis. Four developed significant thrombocytopenia (less than 100,000 platelets per cubic millimeter), and the other nine showed either minimal depression or no change in their platelet levels. Eleven of these patients survived; the two deaths occurred in patients with gastrointestinal hemorrhage. In one instance death was attributed to aspiration following hematemesis (case 17) and in the other to protracted shock following subtotal gastrectomy (case 22). In one instance (case 22) direct transfusion of blood from donor to recipient using silicone-coated syringes was evaluated. The recipient's platelet count before transfusion was 150,000 per cubic millimeter. Five hundred milliliters of whole blood from a donor whose platelet count was 365,000 per cubic millimeter was given by the multiple syringe technique. Immediately after the transfusion the recipient's platelet count was 121,000 per cubic millimeter.

TABLE 3.—*Platelet Levels After Transfusions of from 500 to 4,500 Milliliters of Whole Blood*

Case No.	Age (Yr.), Race, and Sex	Diagnosis	Pre-Transfusion, Platelets/ Cu. Mm.	Total Blood Given, Ml.*	Post-Transfusion, Platelets/ Cu. Mm.†	Outcome	Remarks
15	73 W M	Excision of abdominal aneurysm	183,000	4,500	82,000	Survived	No abnormal bleeding
16	38 W M	Pulmonary tuberculosis; right upper lobectomy; thoracoplasty	......	3,500	105,000	Survived	No abnormal bleeding
17	51 W M	Gastrointestinal hemorrhage; ? duodenal ulcer; no surgery	Normal on smear	3,500	161,000	Died	No generalized bleeding; aspiration after hematemesis
18	68 W M	Excision of abdominal aneurysm	259,000	3,000	105,000	Survived	No abnormal bleeding
19	54 W M	Excision of abdominal aneurysm	195,000	3,000	93,000	Survived	No abnormal bleeding
20	45 N M	Excision of thoracic aneurysm	196,000	2,500	86,000	Survived	No abnormal bleeding

* Total blood given within a 48 hour period. † Lowest post-transfusion platelet count.

Exchange Transfusions for Hemolytic Disease of Fetus or Newborn Infants—Five newborn infants received from one to three exchange transfusions of 500 ml. of whole blood for hemolytic disease of fetus and newborn due to anti-D antibody (table 4). All of the transfusions were performed with type O, cde whole blood that had been drawn within the preceding 24 hours. The infants had been given a vitamin K analogue at birth, and all were given calcium gluconate intravenously at the time of the exchange transfusions. After the exchange transfusions, each of the infants developed significant thrombocytopenia. Two of the five (cases 28 and 30) developed evidences of an abnormal bleeding tendency. One (case 28) developed cutaneous petechiae, ecchymoses, hematuria, and rectal bleeding, and the other (case 30) developed cutaneous petechiae. All of these patients survived. Two other infants with hemolytic disease due to anti-D antibody were studied. In one, the disease was mild. In the other, the disease was moderately severe, and the total serum bilirubin level rose to 18 mg. per 100 cc. Neither of these patients received exchange transfusion. Their platelet counts were normal at birth, and neither developed thrombocytopenia. A summary of an illustrative case follows

CASE 30.—A newborn, white male infant of an Rh-negativ mother was jaundiced at birth. The mother was known to hav been previously sensitized, and this was her sixth pregnancy Prenatal studies showed the presence of anti-D antibody in th mother's serum. Laboratory studies on the infant four hours afte birth revealed: hemoglobin 13 gm. per 100 cc., total seru bilirubin 13.6 mg. per 100 cc., platelet count 410,000 per cubi millimeter, and direct Coombs' test positive. Because of increas ing bilirubinemia, an exchange transfusion of 560 ml. with typ O, cde, *fresh whole blood was performed six hours after birt* During the course of the exchange transfusion the patient wa given 5 ml. of 10% calcium gluconate intravenously. A platel count performed on the donor blood was 171,000 per cub millimeter. Two hours after completion of the exchange tran fusion, the infant's platelet count was 76,000 per cubic mill meter. On the next day petechiae were noted in both axillas. A this time the total serum bilirubin level was 10 mg. per 100 c and the platelet count was 83,000 per cubic millimeter. Th jaundice rapidly subsided, and the patient made an uneventf recovery. On the fourth day of life the platelet count was 124,00 per cubic millimeter; on the fifth day, 150,000 per cubic mill meter; and on the sixth day, 306,000 per cubic millimeter.

The patients in cases 31 and 32 were white male twin with hemolytic disease due to anti-D antibody. Bot required exchange transfusions. Their courses are sum marized in figure 3.

COMMENT

Twenty-seven adult patients and five newborn infants who received one or more whole blood transfusions were studied. Thrombocytopenia was observed t occur in all five infants who received exchange transfusions and in the 14 adult patients who received more than 5,000 ml. of whole blood within a 48 hour period. Eleven of the adults and two of the infants developed clinical evidences of abnormal bleeding. None of the 13 adult patients who received less than 5,000 ml. of whole blood developed clinical evidences of abnormal bleeding, although some did develop mild thrombocytopenia. The thrombocytopenia that was observed was related to the administration of whole blood transfusions. It was observed after transfusions in patients undergoing a variety of surgical procedures, in patients receiving transfusions for gastrointestinal bleeding and undergoing no surgical procedures, and in infants undergoing exchange transfusions for hemolytic disease of fetus and newborn.

The degree of thrombocytopenia was related to the amount of blood given and to the rate of infusion (fig. 4). Significant thrombocytopenia was not encountered when patients received small increments of blood over a period of days or weeks even though the total amount was large, nor was thrombocytopenia observed in patients who underwent surgical procedures but did not receive blood transfusions. Eleven of the adult patients who developed thrombocytopenia after the rapid infusion of more than 5,000 ml. of whole blood exhibited clinical evidences of abnormal bleeding. Seven of these patients developed moderate to severe bleeding that contributed significantly to morbidity and mortality. Four were subjected to exploratory surgical procedures in a futile search for a local cause of the continued hemorrhage. Two patients developed severe gastrointestinal bleeding. In several, continued brisk bleeding from the operative site probably contributed to the protracted hypotension that was the most common feature among the patients who died. In four instances the hemorrhagic diathesis was only of moderate proportion manifested by cutaneous petechiae, mild hematuria, or slightly excessive bleeding from the operative site. All five infants who received exchange transfusions for hemolytic disease developed marked thrombocytopenia, and two displayed clinical evidences of abnormal bleeding. In one (case 30), cutaneous petechiae were noted, and the other (case 28) developed serious bleeding manifested by petechiae, ecchymoses, rectal bleeding, and hematuria.

TABLE 4.—*Platelet Levels After Exchange Transfusions in Newborn Infants with Hemolytic Disease*

Case No.	Pre-Transfusion, Platelets/Cu. Mm.	Total Blood Given	Post-Transfusion, Platelets/Cu. Mm.*	Outcome	Remarks
28	Normal on smear	3 exchange transfusions (500 ml. each)	41,000	Survived	Petechiae; ecchymoses; rectal bleeding; hematuria
29	198,000	1 exchange transfusion (500 ml.)	62,000	Survived	No abnormal bleeding
30	410,000	1 exchange transfusion (765 ml.)	76,000	Survived	Petechiae
31	186,000	2 exchange transfusions (500 ml. each)	50,000	Survived	No abnormal bleeding
32	243,000	2 exchange transfusions (500 ml. each)	31,000	Survived	No abnormal bleeding

---

* Lowest post-transfusion platelet count.

Other studies of hemostatic function were performed in seven of the patients who exhibited abnormal bleeding (table 2). Only one patient (case 1) had a prolonged whole blood clotting time. No circulating anticoagulant could be detected in this patient's plasma. Hypoprothrombinemia occurred in three of these patients. In two (cases 4 and 12) the hypoprothrombinemia could be explained on the basis of other factors in these patients and probably had no relationship to the multiple transfusions. In the other (case 8), the hypoprothrombinemia occurred in association with hypofibrinogenemia and thrombocytopenia. It is possible that in this patient (case 8) the pathogenesis of the hemorrhagic diathesis might have been related to the entrance of thromboplastic substances into the blood stream with resultant intravascular defibrination. This was the only instance of hypofibrinogenemia encountered in this series of patients, and it seems clear that fibrinogenopenia was not the cause of the abnormal bleeding that followed multiple transfusions. A hemorrhagic diathesis has been described in patients after extensive thoracic surgery, and the abnormal bleeding

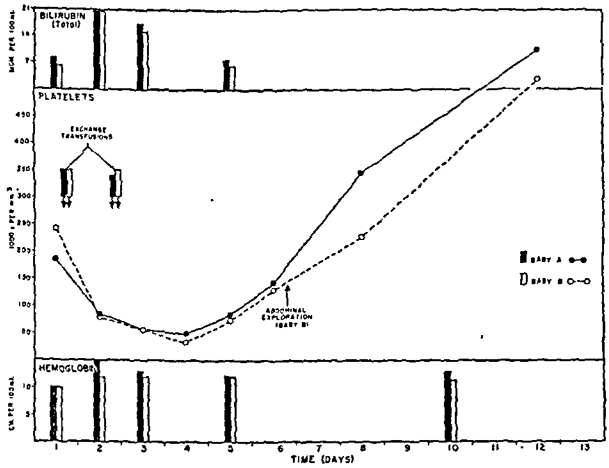

Fig. 3.—Summary of course in newborn twins with hemolytic disease (cases 31 and 32). Exploratory laparotomy was performed in baby B (case 32) because of vomiting. No evidence of intestinal obstruction was found.

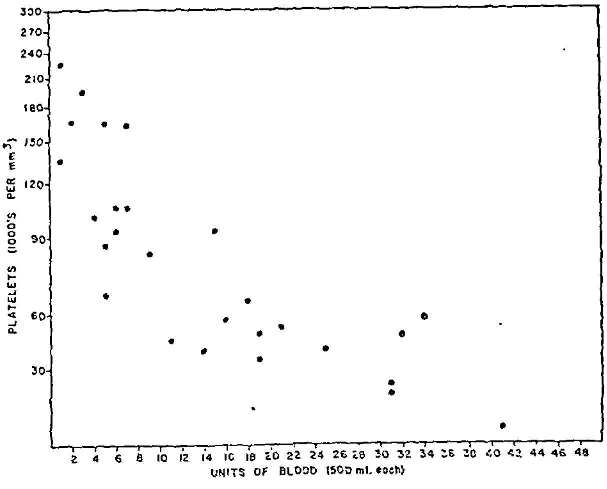

Fig. 4.—Scatter diagram showing the relationship between the amount of blood transfused and the platelet levels. Abscissa—amount of blood administered within a 48 hour period; each unit represents 500 ml. of whole blood. Ordinate—lowest platelet level after transfusions.

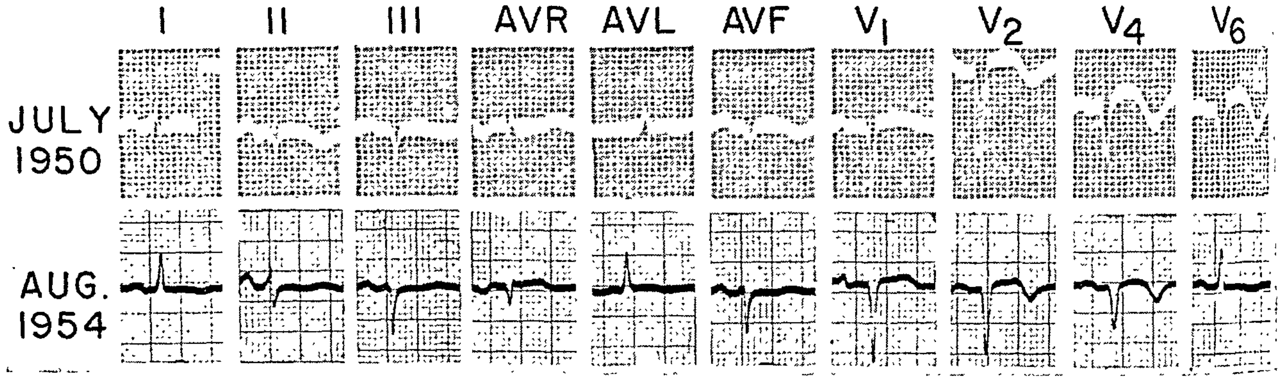
at least 10 years and have instituted a treatment as outlined in this presentation in a large number of patients with encouraging results. Publication of the following data was deemed warranted when recently four cases were encountered in one week. It is hoped that clinicians may benefit from awareness of this condition and the ease with which it may be confused with coronary artery disease.

SYMPTOM COMPLEX

The symptom complex consists of a painful affection of the somatic structures of the anterior chest wall associated with exquisite tenderness on fingertip pressure. It occurs very commonly after coronary occlusion; however, it may be encountered in healthy individuals. Histological changes in the soft tissues of the anterior chest wall are inconsistent. When present, they consist of lymphocytic infiltration in the connective tissue, muscular degeneration, and increase in collagen fibrils. The condition is readily confused with coronary artery disease. *Response to corticotropin (ACTH), radiation therapy, and breathing exercises is prompt.* The cause is unknown; however, it appears probable that this condition is analogous to the shoulder-hand syndrome insofar as its pathogenesis is concerned.



Electrocardiograms of patient in case 2 taken four years apart. Tracing taken in 1954 shows higher R waves and indicates less myocardial damage than the one taken in 1950. It is believed the attacks of chest pain in the four-year period were exacerbations of the anterior chest wall syndrome and not new infarcts.

Clinically, the condition has been encountered only in adults between the ages of 30 and 75 years, with the majority of cases in persons above 45 years of age. This age factor is accounted for by the fact that a large number of the patients developed the condition after an attack of coronary occlusion and hence were in the so-called coronary age group. We have no knowledge concerning the appearance of the condition in children. The condition occurs very commonly from four to six weeks, and occasionally several months, after coronary occlusion. In a small proportion of the cases, the pain begins in the days after coronary occlusion. If the condition is not related to coronary artery disease, the history is usually negative. The symptomatology does not vary depending on the origin of the condition; however, for the sake of simplicity, the postinfarction type of this symptom complex will be described hereafter.

Postinfarction Variety of the Syndrome.—During convalescence after an acute attack of coronary occlusion, or less frequently a few months after discharge from the hospital, the patient begins to complain of recurrence of pain in the anterior part of the chest. The pain is usually continuous and spreads throughout the anterior chest wall with no radiation to neck, jaw, or arms. It is usually most severe in the sternal region and precordium. Patients are often aware of the superficial localization of the pain and occasionally express the opinion that the pain is different from the pain of their previous "heart attacks." The pain is subject to spontaneous exacerbations sometimes indistinguishable from an attack of angina pectoris. Unlike angina pectoris, however, the exacerbations are not accompanied by radiation of pain to the neck, jaw, shoulders, arms, and fingers; they are not brought on by physical exertion and are not associated with vasomotor changes such as salivation and perspiration. The onset of exacerbations may be sudden and is often occasioned by a quick movement of the body. The duration is a matter of hours; the termination is usually gradual. Patients are not generally free of pain in the interim between the attacks. Certain positions of *the body and movements of the chest may provoke an* acute exacerbation of pain; those most frequently reported are anterior flexion or posterior extension of the neck and trunk, lateral rotation of the chest, rotations of the neck, and elevation of the arms. There is no relationship to quantity or quality of food. Emotional stress seems to have an aggravating effect. The pain is present and of the same intensity during hours of activity, but it subsides during the night. Nocturnal attacks of pain are uncommon; however, they occasionally awaken the patient only to disappear with change of body position. If not properly handled, the pain tends to persist for months, and even years. It is often severe and incapacitating. The acute exacerbations may be so excruciating that repeated doses of narcotics are required for relief. Glyceryl trinitrate (nitroglycerin) is without effect.

The condition does not make general health deteriorate and is not associated with systemic symptoms; however, the fear of heart attack in a patient with neurotic background may lead to aggravation of the underlying psychological imbalance. Many patients give a history of having been admitted to numerous hospitals and have visited many physicians for treatment of what they consider persistent heart disease. Some have received narcotics for the acute exacerbations of the pain. Addiction to narcotics is not rare. Mental depression and anxiety neurosis are commonly encountered in patients suffering from this condition.

On physical examination the remarkable finding is tenderness of the anterior chest wall. The area of maximal tenderness corresponds to the points of greatest pain, usually the sternochrondral regions and the areas overlying the cardiac apex. Although the soft tissues are sensitive to touch, the tenderness is more pronounced on pressure over the cartilages and bones. Pressure over the tender areas provokes a severe local pain without radiation. The area of maximal tenderness may migrate from one part of the chest to another. Pain is elicited by pressure on any part of the chest. This fact is important from the diagnostic point of view, since it demonstrates that the tenderness in this symptom complex is different from the so-called trigger zone described by Weiss and Davis [1] and Travell and her associates [2] that, when pressed, produces pain in distant areas such as the heart. The skin possesses normal color and texture. Surface temperature is normal; there are no dysesthesias and no evidence of radicular or truncular nerve involvement. Pressure on the spinous processes does not produce pain. There are no visible or palpable structural alterations of the chest wall. Inflammatory and trophic changes are absent. The breasts are free of demonstrable pathology. Examination of the remainder of the body shows no abnormality associated with or related to this symptom complex. Blood cell count, erythrocyte sedimentation rate, urinalyses, and x-rays are normal. There are no laboratory signs of inflammation, hypersensitivity, infection, or metabolic aberrations associated with the condition. Electrocardiograms taken during the acute exacerbations, as well as those taken between the attacks, remain unchanged. Hyperventilation is frequently seen among patients suffering from this type of pain. The electrolyte disturbances that occasionally result from hyperventilation lead to minor electrocardiographic changes that, under the circumstances, are easily misinterpreted as indicative of coronary insufficiency.

HISTOPATHOLOGY

Biopsies have been performed in a small number of cases and hence are of limited statistical value. The results show, however, that the histological changes are variable. In one case, that of a patient who had this condition for seven years, biopsy of the skin and underlying soft tissues, intercostal muscles, and cartilage of the rib showed lymphocytic infiltration, some muscular degeneration, and evidence of chronic inflammation in the perichondrium as well as the connective tissues surrounding it. In the second case, in which the condition had been present for three years, the only positive finding was a moderate increase of collagen fibrils without concomitant evidence of cellular infiltration. Three biopsies performed in patients with a history of disease of less than a year's duration yielded normal results.

DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS

A positive diagnosis depends critically on the index of suspicion maintained for this syndrome. The persistence of chest pain after an attack of myocardial infarction should always be regarded as highly suggestive of the postinfarction variety of this syndrome. This is particularly true if the pain is not associated with other manifestations of coronary artery disease. However, as the syndrome occurs in individuals without coronary disease, a positive history of myocardial infarction is not to be regarded as a *sine qua non* of this syndrome. Even though the incidence of the postinfarction variety of this syndrome is much higher than that of the variety unassociated with coronary disease, the latter occurs with sufficient frequency to warrant its consideration in otherwise healthy persons complaining of persistent anterior chest pain.

In the differential diagnosis between this symptom complex and other conditions, one must consider all affections leading to persistent pain of the anterior chest wall. Coronary artery disease is the diagnosis most commonly entertained; however, patient questioning and careful physical examination will reveal certain major differences: 1. The pain in coronary artery disease, namely, angina pectoris, is paroxysmal and precipitated by such factors as physical exertion and emotional tension. Attacks of angina pectoris are often preceded by heavy meals and are short; pain of the anterior chest wall syndrome tends to be continuous, with acute exacerbations. Physical exertion and emotional tension do not appear to play an important role in precipitating acute exacerbations. 2. Radiation of the pain in angina pectoris may be characteristic, while pain of this condition does not radiate outside the boundaries of the thoracic cage. 3. The vasomotor accompaniments of angina pectoris are absent in this condition. 4. A continuous pain of coronary origin is apt to be due to coronary occlusion or severe coronary insufficiency, which are invariably associated with other symptoms and signs. Pain of this condition, although continuous and of long duration, is associated with no systemic, respiratory, or cardiac symptoms. Temperature, erythrocyte sedimentation rate, and blood cell counts remain normal. 5. Electrocardiograms taken during the paroxysmal exacerbations of pain in coronary artery disease often show S-T and T changes that may be characteristic; these are not found in the anterior chest wall syndrome. 6. Pain of angina pectoris is relieved completely or partially with glyceryl trinitrate. Pain of this condition fails to respond to this therapy. 7. Although some tenderness of the chest wall may be present in angina pectoris, it is usually mild and tends to disappear after termination of the attack, whereas tenderness in this condition is persistent and exquisite. 8. Finally, prompt improvement with a therapeutic diagnostic test with corticotropin, cortisone, and radiation therapy may provide a clue to the correct diagnosis, for these measures are of no avail in patients with angina pectoris or coronary insufficiency.

An important and relatively common source of anterior chest pain is hypertrophic osteoarthritis of the cervicodorsal spine associated with involvement of the posterior roots.[3] However, the presence of tenderness over the spinous processes and the anterior portion of the intercostal spaces, the characteristic distribution of neurological signs and symptoms, and the x-ray findings of osteo-

3. Sampson, J. J.: Problems in Recognition of Coronary Heart Disease, Geriatrics **9**: 251, 1954.

arthritis are usually sufficient to substantiate the correct diagnosis. Esophageal hiatal hernia frequently causes anterior chest pain; however, this condition is associated with certain digestive symptoms and can be readily diagnosed roentgenologically with the use of proper technique. Tenderness of the chest wall is absent in hiatal hernia. Affections of the mediastinum, pleura, and pericardium can be diagnosed with reasonable ease. Diseases of the bone involving the ribs may create symptom complexes similar to the anterior chest wall syndrome. Among these, metastatic involvement of the ribs, eosinophilic granuloma, and multiple myeloma may be recalled, all of which have specific x-ray findings and other corollary manifestations. X-ray of the ribs is negative in the condition under discussion.

Tietze's disease may simulate the anterior chest wall syndrome very closely. In this condition, according to the available literature,[4] pain and tenderness are limited to the costal cartilages and the superjacent tissues. The cartilages most commonly involved in Tietze's disease are those of the second ribs. There may be visible hypertrophy and tumefaction of those cartilages. The history of patients with Tietze's disease reveals factors such as trauma, respiratory infection, and malformation of the dorsal spine. In the condition under study, on the other hand, tenderness is diffuse and generally lower than the level of the second rib. The history, insofar as the factors mentioned above are concerned, is negative.

Other musculoskeletal conditions of the chest wall may be hard to distinguish from the syndrome under discussion. Muscle strain is usually preceded by violent exercise and is of short duration. It is seen in athletes and people involved in strenuous muscular work. Pain resulting from direct trauma to the anterior chest wall may be diagnosed by a careful history. Neurological affections that give rise to neuralgias may closely simulate the anterior chest wall syndrome; however, the distribution of the objective and subjective sensory changes in the territory of the involved nerves is sufficient to allow one to differentiate between the two conditions.

The disease often feared in women is carcinoma of the breast. Not infrequently, women suffering from pain of the anterior chest wall show great anxiety about breast malignancy. As a matter of fact, cancerphobia is a not uncommon outcome of this condition, apparently due to its persistence and its failure to respond to palliative therapy. Painful diseases of the breast, particularly the various forms of chronic mastitis, may be closely simulated by this symptom complex. In the former, however, there are objective evidences of induration and hyperplasia, and tenderness is often limited to the glandular substance of the breast. Furthermore, that part of the thoracic cage on which the breast lies is not tender on pressure, as can be shown by pushing this organ to one side and examining the subjacent ribs and the intercostal spaces. In the anterior chest wall syndrome, tenderness on pressure over the musculoskeletal structures underlying the breast persists after this organ is pushed away from its normal position.

Since the basic process responsible for pain of
anterior chest wall may involve areas other than th
mentioned earlier, it may resemble diseases of the g
bladder and other subphrenic viscera. We encounte
one patient in whom the condition involved the anter
lower part of the chest wall on the right. This patient

tropin and corticosteroids have not presented any problem in these cardiac patients. We have seen no evidence of coronary circulatory insufficiency after the conclusion of therapy in our patients. It is not uncommon to see recurrence of pain after discontinuation of therapy; the recurrences, however, respond to the therapy outlined above as readily as the original condition. Breathing exercise, as prescribed by a physical therapist, is of unquestionable usefulness. It strengthens the respiratory muscles that, due to the pain associated with deep breathing, may have undergone disuse atrophy. Hyperventilation usually ceases after patients lose their anxiety and are reeducated toward restoring normal breathing habits.

If anxiety is a prominent feature, it may be desirable to use procaine infiltration, for psychological reasons only, to eliminate the tenderness and pain momentarily and enable the patient to see that his pain is not of cardiac origin. This technique may be of sufficient persuasiveness to remove the fear of physical exercise and facilitate further therapy. A significant proportion of these patients are taking digitalis and coronary vasodilators, perhaps unnecessarily. It is advisable to discontinue use of these drugs if indications are lacking.

It is to be added at this juncture that the condition under discussion may be associated with angina pectoris. Great caution must be exercised in evaluating a patient's signs and symptoms in the light of careful history and physical examination. If necessary, hospitalization must be advised for the purpose of evaluation. The treatment of patients suffering from both conditions is obviously more complicated than the treatment of patients afflicted with the anterior chest wall syndrome alone; however, the therapy that has been outlined for the syndrome will abolish those components of the symptomatology accounted for by the condition and hence has diagnostic value. As pointed out earlier, a therapeutic test with corticotropin, cortisone, or x-ray therapy is quite safe in patients irrespective of the condition of the coronary arteries. After a period of approximately a week, treatment with the agents mentioned above will eliminate the somatic component of the chest pain and reevaluation of the patient will reveal the presence of true angina pectoris.

It is to be pointed out that, in evaluating electrocardiographic findings of patients suffering from anterior chest pain, one must be cognizant of certain S-T segment and T-wave changes that occasionally occur with anxiety, fear, and other circumstances in which functions of the anatomic nervous system are disturbed. One must recognize the prevalence of anxiety in patients suffering from this symptom complex so that the value of electrocardiographic findings mentioned above will be properly appreciated.

REPORT OF CASES

CASE 1.—A 44-year-old housewife sustained a posterior myocardial infarction in January, 1954, for which she was hospitalized in another city for six weeks. After discharge from the hospital, she was completely asymptomatic until April, 1954, when she suffered a severe attack of anterior chest pain diagnosed as coronary insufficiency. Electrocardiograms and other laboratory procedures, however, failed to show any changes over the previous ones. The patient continued to have mild, steady anterior chest pains after discharge. This pain persisted and became much more severe about six weeks before admission to this hospital. During this time, she received various coronary vasodilators without relief. There had been no systemic symptoms associated with the pain. The pain was most severe in the midline and the medial end of the second to the fifth intercostal spaces. It was described by the patient as "soreness" and "different from the attack in January." It was aggravated by violent movements and rotation of the chest. Posterior extension of the chest brought about a feeling of "pull" on the anterior chest wall. At no time was the pain associated with dyspnea, thoracic oppression, vascular collapse, or weakness. It did not radiate to the left upper extremity. During the months of bed rest and continuous chest pain she became profoundly depressed and was constantly aware of the fact that she was a cardiac cripple. Numerous drugs had been administered to no avail.

On physical examination she appeared to be in good health. Temperature, white blood cell count, sedimentation rate, and x-ray of the chest were normal. The heart was normal in size and by auscultation. The electrocardiogram was characteristic of an old posterior myocardial infarction. There were no S-T and T changes. The only striking finding was a diffuse tenderness of the soft tissues of the anterior chest wall and the costal cartilages of both sides. The area of tenderness extended from the clavicles to the xiphoid process and laterally to the anterior axillary lines. The tenderness was exquisite on the cartilages and the adjacent intercostal spaces of the right third to fifth ribs. The pectoralis muscles were also tender on pressure. The patient was immediately given permission to move about at will. She was told that her pain was not of coronary origin. It was noted that physical exercise did not precipitate any pain or aggravate the already existing pain. The pain disappeared for the first time in several months after the patient was given corticotropin, 100 mg. for four days. At the end of this period, corticotropin was withdrawn. This was followed by prompt return of the symptoms. She was then given a course of x-ray therapy in order to determine whether the response to this therapeutic agent would be as satisfactory as it was to corticotropin. After four days of x-ray therapy, the pain disappeared completely. The patient is now asymptomatic and enjoys good health. From an emotional point of view she has improved remarkably.

This case demonstrates the ease with which this symptom complex, when occurring after coronary occlusion, may be interpreted as angina pectoris and coronary insufficiency and treated as such. Furthermore, it illustrates the prompt, favorable response to corticotropin and x-ray therapy. It also demonstrates the usefulness of corticotropin and x-ray therapy as agents for diagnostic tests.

CASE 2.—A 54-year-old housewife was first seen on Nov. 1, 1954. Her chief complaint consisted of persistent anterior chest pain of five months' duration. Her cardiac history dated back to January, 1950, when she suffered an acute myocardial infarction. She was placed in another hospital for four weeks and was free of symptoms upon discharge. The patient remained asymptomatic until January, 1952, when she had her second attack. This time, however, no "fresh infarction" was found, and the patient continued to enjoy good health until February, 1953. Since that time, she had been subject to numerous attacks of chest pain of varying intensity. She was hospitalized on six occasions for acute attacks of chest pain diagnosed as coronary insufficiency, for which she was given anticoagulants and other cardiac drugs for varying periods of time. Symptoms of menopause appeared and aggravated the previously existing symptoms. The attacks of chest pain, most of which were recognized as coronary insufficiency, appeared with greater frequency. She began to suffer from a continuous, mild pain in the interval between the attacks. During one of her hospitalizations she was given digitalis, presumably for rapid heart action, and was maintained with this drug until the time of admission to this hospital.

During the five months preceding her admission to this hospital, she suffered from a persistent, severe chest pain with numerous exacerbations diagnosed variously as coronary insufficiency, gallbladder pain, and psychoneurosis. She was given a variety of drugs by a number of physicians whom she had consulted for the acute attacks of pain. Numerous electrocardiograms were taken in this period of time, and they were all identical; however, judging by the size of the R wave, electrocardiograms denoted improvement, as the R waves increased in height over the period of four years, although the patient was hospitalized five times with a presumptive diagnosis of myocardial infarction. When she was seen in this hospital, the patient described her pain as continuous, drawing, and superficial. The pain was associated with a sensation of squeezing pressure on the lateral chest walls and tightness in the skin overlying the sternum. She stated that the pain under discussion, unlike the anginal attacks with which she was familiar, was not accompanied by dyspnea, weakness, sensation of heaviness, and radiation to the left upper extremity. Furthermore, it was not relieved by glyceryl trinitrate. Her history and family history were unrevealing.

Physical examination showed a normally developed, healthy-looking female. Extreme anxiety and frustration were evident in her facial expression. There were no outward signs of heart failure. The heart was moderately enlarged, with the apex beat between the midclavicular and anterior axillary lines. There was a grade 2 systolic murmur at the apex. The heart otherwise was not remarkable. There was a marked tenderness over the major portion of the anterior chest wall, and it was most exquisite near the xiphoid process and in the medial portion of the second, third, and fourth intercostal spaces and the adjacent structures. The skin overlying these areas was not different from the skin of the adjacent normal regions. It appeared to the examiner that both soft tissues and the underlying cartilages were the seat of tenderness. The breasts appeared normal. There was no evidence of nerve involvement. The electrocardiograms showed the old anterior myocardial infarction with some degree of S-T segment elevation in V_1 to V_4. This was not considered to be indicative of coronary insufficiency, as it had been present in all the tracings obtained in the period of less than four years since she had recovered from the first attack of myocardial infarction (see figure).

Chest x-ray showed moderate cardiac enlargement with normal pulmonary vascular markings. This patient was given cortisone, 100 mg. daily for four days. The chest pain began to subside on the third day and was completely absent after four days of therapy. At present she is completely asymptomatic. Incidentally, she was advised to stop taking digitalis, quinidine, and bishydroxycoumarin (Dicumarol), which she had been taking for some time before her admission to this hospital. This improved her cardiac function considerably.

This case also demonstrates how the anterior chest wall syndrome is misdiagnosed and treated as persistent coronary insufficiency. Surprising is the fact that, in spite of stationary electrocardiograms and normal white blood cell count, sedimentation rate, and cardiac functions, the patient's pain was thought to be of coronary origin by all the physicians she consulted during the period of four years. The importance of awareness of this symptom complex and the value of the therapeutic test with corticotropin is again exemplified.

Case 3.—A 50-year-old housewife was seen in November, 1954, because of a continuous chest pain of 12 years' duration. She suffered an acute attack of coronary occlusion in 1942, after which she developed anterior chest pain that persisted up to the time of admission to this hospital. She consulted numerous physicians, all of whom confirmed the diagnosis of persistent coronary insufficiency and advised restriction of physical activity; however, the pain was not precipitated by physical exertion or emotional tension. No relationship of the pain to heavy meals was noted. Glyceryl trinitrate was ineffectual. The patient was subject to paroxysms of pain, some of which occurred during the night upon change of position in bed. The patient volunteered the information that the chest was sore on touch, and the soreness was associated with a feeling of tightness of the chest wall. She suffered another attack of coronary thrombosis in May, 1953. She recovered from this attack uneventfully but continued to have the above-mentioned persistent anterior chest pain. After the death of her husband, she was forced by her economic status to accept an eight-hour-a-day job as a salesgirl, which necessitated standing on her feet for hours at a time. This was done in spite of her previous physician's advice to the contrary. She w highly surprised when she found herself perfectly capable handling the job.

Physical examination revealed a healthy-looking female wi a nervous appearance and noticeable facial flush. No respirat distress and no evidence of heart disease were noted. There w no signs of hyperthyroidism. The most significant physi finding was tenderness of the anterior chest wall, which was m exquisite in the center of the sternum and decreased radially. T tenderness seemed to be in the bony structures as well as the sk The heart was slightly enlarged to the left. There were no ot significant physical findings. This patient was given reassura and was persuaded that her pain was not of cardiac origin. S was urged to keep her job. At present she is working efficie and has no symptoms.

This case demonstrates that reassurance per se m be all that is necessary for removing phobia of he disease, after which the patient learns to endure the ch pain without anxiety.

Case 4.—A 61-year-old housewife was admitted to the Ce of Lebanon Hospital clinic on Nov. 21, 1954, with a histor chest pain of three to four years' duration. The history of h disease dated back to 1932, at which time she suffered f dyspnea and was digitalized. She continued to have some e tional dyspnea but was active physically. Three to four years fore admission, she began to have periodic anginal attacks, a as time went on, she became more and more dyspneic, wi significant diminution in her physical capacity. The anginal tacks consisted of a feeling of pressure and heaviness on chest, with radiation of pain to the left shoulder and down left arm. She had been taking glyceryl trinitrate with good sults. At the time of admission, she could walk only a frac of a block before becoming short of breath. Recently, howe she had been aware of what she called "soreness" of the terior part of the chest wall and left breast. This soreness persistent and, according to the patient, differed from the orig anginal pain. It did not respond to glyceryl trinitrate. It was gravated by lying on the left side. Her history and family tory were unremarkable.

Physical examination revealed a moderately obese fem There were no outward evidences of congestive heart failure. significant finding was an exquisite tenderness of the ante chest wall in the apical region that progressively diminished i directions. It extended to the left clavicle, left border of the num, and left posterior axillary line. The skin overlying the te areas did not seem to be very tender. There were no obje changes in the soft tissues. There were no trigger zones an evidences of neuralgia. The intercostal muscles seemed t exquisitely tender. The most tender spot was on the fifth rib the adjacent intercostal spaces at the nipple line. The heart slightly enlarged, and heart sounds were normal except for a soft grade 1 systolic murmur at the apex. The remainder of physical examination was not remarkable. Laboratory tests w all within normal limits. Electrocardiograms showed prolon P-R intervals averaging 0.26 second. There was wandering p maker and digitalis effect with left ventricular hypertrophy. patient left the hospital before treatment was instituted.

For a number of years this patient undoubtedly h coronary heart disease with angina pectoris on wh the somatic type of pain was superimposed.

Case 5.—A 75-year-old female was admitted to the Cedar Lebanon Hospital clinic for recurrent attacks of chest p on Nov. 20, 1954. The electrocardiogram taken before admis showed left bundle-branch block that was thought to favor di nosis of recent myocardial damage. She had had high bl pressure and "heart trouble" for 15 years and had been tak digitalis for the same period of time. Five months prior to adm sion, this patient suffered a severe heart attack diagnosed as m cardial infarction. She had been incapacitated and suffered fr innumerable attacks of anterior chest pain since the attack coronary occlusion. In addition to the episodic anginal pain, had been conscious of a persistent dull ache over the anter chest wall that was most severe at the apical region for two months. Her history and family history were noncontributory.

On physical examination the striking finding was a marked tenderness over the left anterior chest wall that was most severe and excruciating at the apical region of the heart, where the maximal pain was felt. The tenderness decreased in a radial fashion, and it extended as far up as the clavicle and as far back as the posterior midline. The tenderness was associated with a severe pain, which was continuous and uninterrupted, involving the same areas and often misdiagnosed as anginal pain. There had been no signs or symptoms of congestive heart failure during the present hospitalization. The presence of tenderness over the chest wall was believed to speak in favor of somatic anterior chest pain. This patient did not stay in the hospital long enough for institution of treatment.

This case demonstrates that such nonspecific electrocardiographic changes as bundle-branch block in the presence of the somatic chest pain strengthen the suspicion for coronary artery disease and resultant myocardial damage. An abnormal electrocardiogram does not make the diagnosis of active heart disease.

Case 6.—A 27-year-old housewife was seen in 1950 because of a seven year history of unremitting precordial pain, appearing most commonly after meals or upon emotional upheavals. The pain was described as sharp and penetrating and of sufficient severity to warrant the use of narcotics on many occasions. Numerous diagnoses were entertained, namely, coronary artery disease, cardiospasm, esophageal hiatal hernia, and psychoneurosis, but none was substantiated. The only significant point in her history was an automobile accident resulting in brain concussion four years before the onset of chest pain. The patient had been of a nervous disposition all her life. She had become addicted to meperidine (Demerol) hydrochloride approximately one year before her first visit.

Physical examination revealed a normal-appearing woman in no distress. Blood pressure, heart rate, lungs, and abdomen were normal. X-rays and electrocardiograms failed to show any evidence of heart disease. The only positive finding was a marked tenderness on the anterior chest wall, which was most intense in the parasternal areas of the second to fourth intercostal spaces bilaterally. Due to this patient's uncooperativeness, it was not possible to administer a complete course of therapy; however, she was impressed when her pain was relieved by procaine (Novocain) hydrochloride infiltration of the soft tissues of the chest wall.

This case exemplifies the occurrence of somatic chest pain in an apparently healthy individual with no history and no evidence of heart disease. Whether there was a causal relationship between the brain trauma and the painful condition that subsequently developed is a matter of conjecture. The patient became addicted to meperidine as a result of persistent pain and unwarranted use of narcotics.

COMMENT

Chest pain following myocardial infarction is most likely to be attributed to coronary insufficiency, angina pectoris, or anxiety neurosis. Actually, a large portion of victims of coronary artery disease are free of anginal pain for the months or years after coronary thrombosis. Contrary to this usual sequence of events, it is not uncommon to encounter patients who, after an attack of myocardial infarction, continue to have a steady soreness of the anterior chest wall unaccompanied by signs and symptoms of coronary artery disease or pericarditis. This condition is not associated with such ordinary accompaniments of angina pectoris as thoracic oppression, heaviness, dyspnea, and flatulence, nor is there radiation to the areas commonly influenced by true angina pectoris. The patients' general health is strikingly good. The pain does not respond to glyceryl trinitrate. A similar type of pain was described as early as 1923 by Wearn,[5] who reported a case of coronary artery occlusion in which a "dull ache" developed over the precordium. The symptom was aggravated by exercise but was not relieved by glyceryl trinitrate. Eckerson and associates [6] wrote in 1928, "It is not uncommon for patients who have suffered coronary thrombosis to be subject for varying periods to a type of thoracic pain which is distinguishable from the ordinary picture of angina pectoris and which is of somewhat different significance." Of the 12 out of 23 patients who survived coronary thrombosis, 3 developed this type of pain. This pain occurred within a few days to few weeks after coronary occlusion. Curiously enough, the association of heart disease with somatic musculoskeletal manifestations was first noted by orthopedists. Thus, King and Holmes,[7] in 1927, noted that a significant proportion of the 450 patients with painful shoulders had heart disease. Howard [8] was first to describe what he called "periarthritis of the shoulder" appearing in the course of coronary thrombosis and again pointed out the association of cardiac disorders and somatic changes of the shoulder. Among the cases of periarthritis reported by this author, one can find four cases in which sustained precordial pain occurred before or after the appearance of stiff painful shoulders. In one of these cases the chest pain subsided when the shoulder pain was cured. Boas and Levy,[9] in a paper dealing with shoulder pain and angina pectoris, cited two cases (cases 1 and 3) in which hyperalgia and tenderness of the chest wall were associated with somatic changes of the shoulder. Askey,[10] in 1941, was first to note that the changes occurring in the shoulder and hand in patients convalescing from myocardial infarction are parts of the same process, hence adding to the understanding of the condition and demonstrating that the symptom complex was not necessarily limited to one joint. Allison [11] wrote in 1950 on pain of the chest wall simulating heart disease and stated that "fibrositic" lesions of the chest wall are very common accompaniments of coronary disease. It is thus evident that visceral changes can give rise to somatic alterations of the adjacent musculoskeletal structures. Perhaps the best example of this phenomenon is the shoulder-hand syndrome that occurs in patients with coronary artery disease and is indistinguishable from that which follows injury to the arm and many other conditions.

A great deal has been written to explain this curious viscerosomatic interrelation. Factors such as disuse, reflex vasomotor changes, summation of impulses similar to the state of affairs that leads to causalgia and poor

circulation, and anoxia secondary to heart failure in cardiac patients have been incriminated. Steinbrocker,[12] and Steinbrocker and his associates,[13] introduced the term "reflex neurovascular dystrophy of the upper extremities." They explained the trophic alterations of the somatic structures on the basis of anatomic connections existing between the afferent visceral nerves and the efferent sympathetic and trophic neurons of the extremities. The impulses from injured myocardium are supposed to enter the spinal cord gray matter, where they pour into the vast internuncial pool. Numerous interconnecting neurons in the internuncial system transmit these incoming impulses to the neighboring motor neurons of the anterior horn (trophic) and posterolateral column (sympathetic). The motor neurons in these vital centers are influenced, leading to muscular dystrophy and vasospasm respectively. The interconnecting neurons of the internuncial system extend over many segments of the spinal cord, whereby impulses entering one segment of the cord can influence motor neurons situated at a significant distance from that segment. One author [11] states that at least one pathway can be found connecting any two central neurons so that impulses may be conducted from one to the other.

The trophic and vascular changes and the secondary inflammatory alterations of the upper extremities occurring after myocardial infarction are explained on the basis of the proximity of the corresponding centers in the spinal cord, resulting in a steady bombardment of the trophic and sympathetic centers of the upper extremities. Actually, from an anatomic point of view, the central motor neurons of the anterior chest wall are just as close to the afferent cardiac nerves as are the motor neurons of the upper extremities. The afferent cardiac nerves enter the cord at the level of C-7 to D-4, where motor neurons of the upper portion of the chest wall are located. Moreover, the rich internuncial system in this area could easily establish connections between the afferent cardiac nerves and the motor neurons of the lower part of the chest. It is entirely possible that somatic anterior chest wall pain is pathogenically analogous to the shoulder-hand syndrome; however, this is pure conjecture. There is no evidence for or against it. If it is assumed, however, that the condition stems from cardiac or other visceral pathologies, one logical basis for explanation of the somatic alterations would be that which utilizes the neurovascular concepts advanced by Steinbrocker.

The mechanism of action of corticotropin, corticosteroids, and x-ray in this condition is unclear. The common denominator among corticotropin, cortisone, and x-ray is probably an anti-inflammatory action against chronic inflammations. It is possible that the beneficial effect of these agents is exerted through their anti-inflammatory action. Admittedly, our knowledge of the pathological physiology and the histopathology of the condition is scanty. The mode of action of the therapeutic agents mentioned above will be more clearly understood when more is known about the pathogenesis of the symptom complex.

SUMMARY AND CONCLUSIONS

The anterior chest wall syndrome is a symptom complex consisting of somatic involvement of the anterior chest wall leading to pain and tenderness. Two distin varieties of this syndrome are the postinfarction variet that begins weeks to months after an attack of acute myo cardial infarction and the variety unassociated with coro nary disease.

Its cause is unknown. It is possible, however, th this condition is pathogenically analogous to the shou der-hand syndrome and hence possibly of neurovascul origin. Histological changes are inconsistent. The cond tion occurs very commonly after myocardial infarctio at varying intervals; however, it has been observed noncardiac individuals and generally lasts months, a even years. It may be associated with angina pector causing persistence of pain and creating a picture easi confused with that of status anginosus.

The symptom complex is often misdiagnosed as cor nary artery disease and treated accordingly. This leads a chain of events in which patients arrive at the convi tion that they have incurable heart disease and devel profound anxiety and depression. The therapeutic mea ures exert their noxious influences to aggravate t symptoms and perhaps add such complications as dr addiction. In such undesirable state of affairs, the ph sician is not spared fear and frustration. The presen of tenderness of the anterior chest wall and absence signs and symptoms of progressive coronary artery d ease are the most important diagnostic features of t symptom complex. Therapeutic tests with corticotrop corticosteroids, and x-ray therapy are generally sufficie to uncover the true nature of the pain.

The response of the symptom complex to proper th apy is usually gratifying. Two to three days of thera with corticotropin or cortisone is often sufficient to bri about much relief of pain. More prolonged treatme with these agents cures the condition completely as rule. If protracted treatment with the corticoids is u desirable, roentgen radiation may be substituted it in two to three days. The full duration of thera does not exceed 7 to 10 days. In the event of recurren of the symptom complex, therapy may be repeated.

The condition is believed to occur very common Its recognition is of great practical importance. It m be advisable that all patients complaining of anteri chest pain, particularly those with a history of myocard infarction, be examined carefully for the presence tenderness of the chest wall. A recent paper by E wards [15] on musculoskeletal chest pain following my cardial infarction clearly describes the postinfarctio variety of this syndrome. Therapeutic tests with cortic tropin, cortisone, and x-ray are entirely safe and m be resorted to with impunity.

IMPORTANCE OF TUBERCULIN TESTING OF SCHOOL CHILDREN—A TWENTY-EIGHT YEAR STUDY

J. Arthur Myers, M.D., Frederick G. Gunlaugson, M.D., Minneapolis, Edward A. Meyerding, M.D., St. Paul
and
Jean Roberts, M.S., Minneapolis

Speaking before the New England Pediatrics Society, Boston, March 12, 1926, Allen K. Krause, Baltimore, said, "It is now almost ten years since a large proportion of the children of your neighboring community of Framinghan was being tested for tuberculous infection. Their infants then have now entered late childhood and their children become youths. If a new series of tests were now performed on Framingham's children, comparable in number, age and condition to those tested from 1917 on, any marked deviation from the figures of a decade ago would render the study one of the most important and significant ever undertaken in the epidemiology of tuberculosis. Standing alone, the results of Framingham's test of 1917 to 1920 mean comparatively little. They merely confirmed what was already common knowledge. But, set over against a new series of records, they might serve to lend scientific support to new concepts of the epidemiology of tuberculosis."[1]

Although we had employed the tuberculin test extensively since 1920 and had sought persons with contagious disease among reactors' associates, we were inspired by Krause's statement to undertake a long-term study. F. E. Harrington, commissioner of health, Minneapolis, arranged for an investigation in 24 parochial schools selected geographically so as to present a good sampling of the childhood population of the city. It was planned to test in these schools about once in 10 years, as this would determine changes that might occur in the tuberculosis infection rate among children from generation to generation and might also be productive of other important information. Tuberculin testing was done in these schools in 1926, 1936, 1944, and 1954. Original tuberculin was administered by the intracutaneous method on each occasion. In 1926 and 1936 the usual two-test method was employed for those who did not react to the first strength. In 1944 and 1954 a single dose of tuberculin consisting of 1 mg. was administered intracutaneously (1 mg. of tuberculin as first dose is not recommended except in low incidence areas). Those who presented areas of induration or edema, or both, of 5 mm. or more in diameter were classified as reactors and all others nonreactors.

RESPONSE TO PROJECT

Response to a school tuberculin-testing program depends largely upon information previously transmitted to parents, personnel, and the children themselves. In 1926, 1936, and 1944 no extensive preliminary educational work was done. Although response improved between 1926 and 1944, at no time was it entirely satisfactory. In fact, it was sometimes stated that one could not hope for as good response in mass tuberculin testing as in mass x-ray surveys. To test the validity of this belief the Committee on Tuberculosis of the American School Health Association in the early 1940's devised a plan whereby schools might be officially certified on the basis of tuberculosis control work in progress. Minnesota was chosen as the demonstration area to determine whether this project could be made practical and effective. A subcommittee consisting of three physicians especially interested in tuberculosis among children was appointed. They prepared qualifications that, if met, would justify official certification of schools. These qualifications were: (1) testing with tuberculin 95 to 100% of children and making x-ray film inspection of the chests of the reactors, (2) testing all school personnel and making x-ray film inspection of the chests of reactors immediately and annually thereafter, (3) completing the examination of all who presented shadow-casting lesions for final diagnosis, and (4) retesting all nonreactors every two years and completing the examination of those who had converted. From the outset this program was popular and created more interest and activity in tuberculosis control in whole communities than any procedure that had ever been introduced.[2] Now 2,100 schools have certificates displayed on their walls, and large numbers of others are well on the way to meet the qualifications. In a four-county sanatorium district Jordan[3] has certified all schools, which means that all personnel cooperated and that the required number of children have been examined.

Since this procedure had not been instituted in a larger city, we decided to test it in our 24 parochial schools in 1954. Tuberculin testing was preceded by an intensive educational campaign over a period of about two months. The nursing staff of the health department and others participated. They met with parent-teacher organizations and conferred individually with principals of schools and other administrators. They distributed explanatory printed material among parents and the entire school personnel. Educational workers of the Minnesota Tuberculosis and Health Association arranged

for newspaper articles and radio and television broadcasts, and a special printed pamphlet describing the tuberculin test was distributed to parents and school personnel. An excellent organization was formed in each school for the actual testing in which mothers of children and health chairmen played an important role. It is doubtful if such a response had previously been experienced and recorded. The whole procedure was so thoughtfully and carefully developed from the time of its announcement to completion that it is being published in some detail in pamphlet form.

School and community pride spurred personnel, parents, and the children themselves on to the certification goal. It served as a powerful incentive. For example, in the first school tested one teacher did not respond. On the day of reading tests 72 hours later, she was the first to appear and requested the tuberculin test, stating that she could no longer take the goading of the other members of personnel, parents, and even several children who asked her if she was going to prevent their school from receiving a certificate. In another school on the morning of testing a kindergarten teacher informed the principal that six children in her room were absent. The principal called each mother by telephone and urgently requested that the children be brought in at least long enough for the test. Five promptly responded.

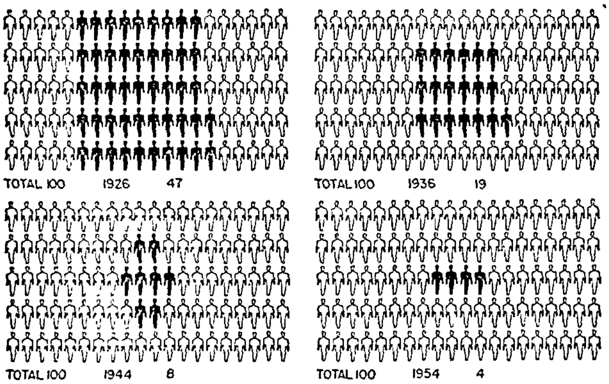

Fig. 1.—Number of tuberculin reactors (black figures) per 100 children for the years 1926, 1936, 1944, and 1954.

RESULTS

In 1926, 47.3% of the children reacted to tuberculin[4] (fig. 1). Evidently this was a definitely lower incidence of infection than had obtained a decade before. Testing in the same city in 1916, Sedgewick[5] found that 70% of the children became infected during the first 14 years of life. Nevertheless, our 1926 tests indicated that almost half of the children had been in contact with tuberculous people or animals or their products. Attempts were then made to afford better protection for the childhood population by adding 200 beds for contagious cases of tuberculosis in the county sanatorium. A hospital with 176 beds for tuberculous veterans was established in Minneapolis, although not all of the patients were from this area. The county medical society, local department of health, and the county tuberculosis association presented each physician with a tuberculin syringe and delivered gratis freshly diluted tuberculin every two weeks. Each physician was asked to administer the test to every person who applied for any kind of examination. This resulted not only in finding an appreciabl number of contagious cases of tuberculosis but also had a fine educational value, both for the medical profession and the public.

The epidemiological work of the health departmen was intensified; and effort was made to examine contact of reported cases. Moreover, many apparently norma children were tested with tuberculin and persons responsible for infecting them were sought. In 1933 and 1934 the school board required its 3,602 employees to be examined for this disease, when 68 were found to have shadow-casting lesions requiring further examination, six of which were already contagious.[6] The veterinary profession had accredited the 87 counties, so the state was designated a modified accredited tuberculosis-free area in December, 1934. The educational work of the tuberculosis association through the sale of Christmas seals was intensified. With these and other activities it seemed that progress should have been made. However, the best measure of success was to test the children who had entered school during the past 10 years. Tuberculin testing in the same grade schools in 1936 showed that the incidence of infected children had decreased from 47.3% 10 years earlier to 18.9%[7] (fig. 1). Thus, approximately four of each five children had been protected against tubercle bacilli.

After 1936 the tuberculosis control program was continued and, wherever possible, intensified. Because F. E. Harrington, commissioner of health, who had made this project possible, was reaching the age of retirement, the next testing was done after eight years. Between 1936 and 1944 the number of unhospitalized, contagious adult cases had decreased. The medical profession was alert, and more unsuspected cases were being found and treated. One private general hospital had established a division for chest surgery. In that division and in physicians' offices collapse therapy converted many contagious cases and prevented many others from becoming contagious. Minneapolis General Hospital established a special chest disease service where persons with pulmonary lesions could be admitted promptly for differential diagnosis. On this service strict contagious disease technique was instituted for the protection of patients, personnel, and visitors and for the education of students and graduates in nursing and medicine. A provision was made whereby recalcitrant patients were placed under quarantine and committed to the sanatorium.

Tuberculin testing in the schools in 1944 revealed 7.7% infected[8] (fig. 1). Thus among each 13 children, one had been unprotected. Between 1944 and 1954 the number of clinical cases of tuberculosis diagnosed decreased so that there was usually no significant waiting list for sanatorium beds. In 1947 a mass photofluorographic survey reached approximately 64% of the adult population. Before this and since, the county tuberculosis association kept mobile x-ray units in almost constant operation. Veterinarians continued their attack on tuberculosis among animals throughout the state with such success that in 1953 only one bovine was found infected in each 5,000 tested. In Hennepin County, where Minneapolis is located, testing of the 45,000 cattle revealed only one reactor. Thus it had become exceedingly rare for a child or an adult to be infected by animals.

[8] Myers, J. A.; Harrington, F. E., and Garcia Suarez, E.: The Importance of Detecting Tuberculosis in Children, J. A. M. A. **128**: 852 (July 21) 1945.

In 1954, of the 11,976 children in these 24 schools, 11,818 (98.7%) were tested with tuberculin. Refusals were rare. Most of those not tested were absent from school on the days of testing because of prolonged vacations and illness. Of those tested, 455 (3.9%) reacted (fig. 1). Among the reactors, 25 (5.5%) were from displaced persons' families or from Mexico, Puerto Rico, or the Philippines, where a high percentage of children are infected. The communities in which these children now reside probably are not responsible for their infections, but they now have the responsibility of keeping them under close surveillance. Figure 2 shows the percentages of reactors by age groups (6 to 14 years) at each testing over the 28 year period. The table shows numbers tested and percentages of reactors by age groups in the 1954 testing. The high percentage at ages 4 and 16 presumably is due to the small number tested.

Among the 432 personnel members (administrators, teachers, clerks, cooks, janitors, and bus drivers) only 7 failed to respond. They were all in one school. Of the 425 tested, 199 (46.8%) reacted. The personnel members belong to other generations who were not so well protected against tubercle bacilli as the present group of children. In fact, some of them passed through infancy and childhood when 70% or more of children were infected in this area, and a considerable number were children when we first tested in these schools in 1926 and found 47.3% infected. The failure of seven personnel members who refused to be tested and thus prevented only one school in 24 from attaining the certification goal is cause for comment. Although they were willing to have x-ray film inspection of their chests, it is well known that persons with clear films may have open sinus tracts on parts of the body covered by clothing from which tubercle bacilli containing material exudes. There are records of personnel members of schools refusing examination who even resigned because of insistence on the part of the administration and who were then found to have contagious tuberculosis of which they had been aware for some time. It was such experiences that caused the American School Health Association to demand that 100% of personnel members be examined before issuing a certificate to any school.

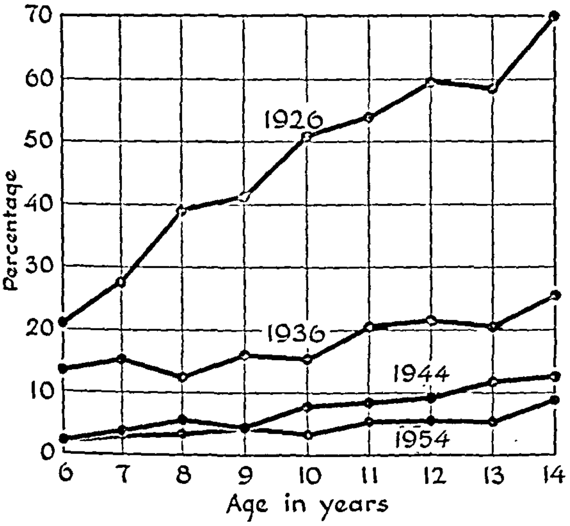

Fig. 2.—Percentage of tuberculin reactors, by age groups, at each testing over the 28 year period.

Tuberculin Reactors by Age Groups, 1954

CASE-FINDING VALUES OF PROJECT

It is well known that tuberculous lesions begin to develop within an hour after tubercle bacilli invade the body.[9] The term infection applies only to the invasion. The minute lesions may progress continuously but much more often intermittently to gross proportions. They may also liberate bacilli that result in new lesions (endogenous reinfections). From the microscopic initial lesions, therefore, either directly or indirectly lesions may evolve to cause illness and even death. Thus infection, lesions, illness, and death represent different phases in the evolutionary process of tuberculosis. Therefore, the individual with microscopic lesions has tuberculosis as certainly as the one dying from the disease. The latter at one time was in the same stage as the former. Moreover, he then had a case of tuberculosis as truly as when he was dying from the disease. Obviously all persons with microscopic lesions have cases and should be so recognized in case-finding programs, whether on a mass basis or in the physician's office.

Within a few weeks after tubercle bacilli invade the individual's body, the tissues, including the skin, are so sensitized to tuberculoprotein as to react characteristically to tuberculin. This reaction is specific and indicates the presence of lesions even while they are microscopic. It is the minuteness, consistency, and location of most lesions of primary tuberculosis complexes that preclude their visualization during life. It was these factors that led to the erroneous concept that infection exists without lesions. The pathological studies of Ghon in the second decade of this century showed that at least primary tuberculous lesions were present in all bodies examined of persons who during life had no detectable evidence of tuberculosis except the tuberculin reaction. This has been confirmed by veterinarians who in this country have made postmortem examinations on approximately 4 million tuberculin-reacting cattle. The 455 children who reacted to tuberculin in this study must be classified as having tuberculosis in the sense that they possess lesions that at any time in the remainder of their lives may evolve to gross and symptom-producing proportions. The superiority of the tuberculin test over all other diagnostic procedures is demonstrated. Of the 455 reactors who had x-ray film inspection of their chests, only 21 (4.8%) showed any abnormality. The findings in these 21 consisted mainly of calcific deposits with undetermined etiology. Biopsy would be necessary for accurate diagnosis.

---

[9] Vorwald, A. J.: The Early Cellular Reactions in the Lungs of Rabbits Injected Intravenously with Human Tubercle Bacilli, Am. Rev. Tuberc. 25:74, 1932.

The importance of periodic examinations of tuberculin reactors who have no other evidence of tuberculosis is obvious. Sweany [10] has shown that nature often reabsorbs the osseous and calcified walls encasing tubercle bacilli in primary lesions and thus liberates tubercle bacilli. From everywhere comes the lament that such a high percentage of cases of clinical tuberculosis are in an advanced stage when recognized. Moreover, mortality among these persons is high. Alling and co-workers [11] reviewed all cases of advanced tuberculosis reported in eight upstate New York counties from 1938 through 1948. In the 224 considered, one-fourth of the persons died in the first six months after diagnosis and almost two-fifths during the first year. The solution of this problem has been thoroughly demonstrated over the past quarter century.[12] All advanced cases could have been found when the tuberculin reaction was the only demonstrable evidence of tuberculosis. From that time on periodic examinations at least annually will permit diagnosis of 95% of evolving chronic pulmonary lesions while they are minimal, before they produce symptoms and usually before they are contagious. Obviously the best time to start routine tuberculin testing is in childhood. Those who do not react should be tested periodically throughout childhood and adult life. Those who become reactors should be examined periodically throughout life, since tuberculosis is a lifetime disease.

SOURCE CASES

Inasmuch as tuberculosis is a contagious disease ar infections are acquired after birth, the tuberculin react has had contact, usually direct, with at least one pers who had contagious tuberculosis. Therefore, the tube culin reaction is an excellent epidemiological age When an adequate search is made among the ad associates of the child who reacts, the contagious case found with such frequency as to justify all efforts a expense. For example, Wood and Mantz [13] tested w tuberculin kindergarten and first grade children Kansas City. On examining the adult associates of reactors, they found 10 times more clinical cases tuberculosis than had ever been discovered in that a by mass x-ray survey. The St. Louis Academy of G eral Practice reported tuberculin testing of 15,7 school children and finding among the reactors and th adult associates 13 times more active cases of tuber losis than the national average with mobile x-ray unit

Where good epidemiological work is practiced, th must come a time when attempts to trace to the sou of infection among tuberculin reactors, particularly older school children, will reveal that most of the sponsible cases have already been found and prop managed. For example, in one entire county where 8 of the persons of all ages beyond 6 years responded tuberculin-testing survey, no case of clinical tubercul was found among the reactors.[15] In that county, p ticing physicians, the medical director of the sanatori and their allies have combed the population for clin tuberculosis for more than a quarter of a century. lesions evolved, they were usually found before they disseminated tubercle bacilli to many of their associa However, the children whom they infected still reac tuberculin. In this particular county, 22% of the t population is harboring tubercle bacilli as manifeste the tuberculin reaction. The percentage is exceedi small among the children and young adults, but as l as 40 to 60% among persons in the later decade life. If the reactors of all ages in this county are ex ined periodically, those in whom clinical lesions destined to evolve will be detected largely before t cases have become contagious. Thus, few new in tions will occur. If the clinical lesions that ev among the tuberculin reactors are found sufficie early, present methods of treatment are capable of venting them from becoming contagious and thus tubercle bacilli can be kept corralled for the remain of those individuals' lives. The present situation in county may be contrasted with another in which cour wide tuberculin testing was offered to all age group 1941. Among the 2,031 reactors examined, 16 alre had clinical tuberculosis.[16]

Following our 1926 and 1936 testing in paroc schools, no effort was made to find sources of the c dren's infections, although intensive work of this k was being done in some of our other studies. Famil of the reactors were contacted with reference to kno sources of exposure, and some effort was made am the contacts of those who did not know when or wh infections occurred. However, soon after the 1954 te ing an investigation revealed that there were 1,744 contacts in the homes of the 455 children who reacted. Plans are under way to examine all of these associates, but to date this has been accomplished in only 1,018 (58.4%). An additional 321 (18.4%) of the contacts were children found to be nonreactors to tuberculin. Examination of the remainder will require considerable time. Of the 1,018 already examined, 945 had no abnormal findings, 9 had suspicious lesions, and 20 had other (thought to be nontuberculous) findings. Fifty-one had been given a diagnosis of tuberculosis, and 13 were earlier suspected of having tuberculosis. Only one new definitely diagnosed case was found, which speaks well for the long-continued search for clinical cases of tuberculosis in these communities. This is in sharp contrast with our earlier work in other groups when numerous unsuspected cases of contagious tuberculosis were found among adult associates of tuberculin-reacting children.[12] Among the 199 personnel members who reacted to tuberculin, 192 have already been examined, of whom 167 presented no chest abnormality. Of the remaining 25, only 3 had parenchymal lesions, each of whom was previously diagnosed and adequately observed or treated. Others had such conditions as rib anomalies and calcified lymph nodes. Two had changes in cardiac outline. This is most satisfying, as it indicates that care has been exercised to keep contagious personnel members from working in schools.

The prediction of Krause in 1926 that tuberculin testing in schools about every 10 years would yield much valuable information has proved true in this study. On another occasion he said that the value of the test will increase as the incidence of tuberculosis decreases. His vision has been so realized that the tuberculin test has become the master key to the tuberculosis problem. It detects the presence of tuberculosis earlier than any other phase of an examination. It is the only accurate yardstick for promptly measuring the effectiveness of a tuberculosis control program. It is our only good method of determining the present and future tuberculosis control program. It can be used to advantage in determining responsibility in cases that come to litigation. It is our best epidemiological agent. It now promises to tell the physician the only time to start treatment if complete cure is to be accomplished. The conventional therapeutic procedures of the past have had no effect on the immediate course of primary tuberculosis either in children or adults nor have they prevented such individuals from subsequently developing clinical lesions. Antimicrobial drugs may completely change this situation. It has recently been recommended by Waring [17] and others that these drugs be administered as soon as possible after the individual converts to a tuberculin reactor. At that time the lesions are small and vascular and may remain so for some months. This is the only time when antimicrobial drugs might be expected to destroy all tubercle bacilli. If the time passes when the blood supply to tuberculous lesions is eliminated there is little likelihood that any drug can reach all bacilli in necrotic lesions. If our present or subsequent antimicrobial drugs prove effective in the numerous investigations now being conducted, it will be the first time in history that physicians have been able to cure tuberculosis. The tuberculin test is the only known procedure by which the disease can be detected at this early stage. Thus, the medical profession will have no alternative but to administer this test periodically to all nonreactors.

The tuberculin test may also serve to determine when adequate treatment has been administered. There is reason to believe that when all tubercle bacilli are destroyed so there is no longer tuberculoprotein maintaining sensitivity of tissues, the individual will cease to react to tuberculin. Only prolonged careful studies, both experimental and clinical, will provide the necessary information. A widespread movement is under way for tuberculin testing school children everywhere. This affords the medical profession its finest opportunity of all time to scientifically and effectively attack this disease with the hope of ultimately tracking down and destroying the last tubercle bacillus.

SUMMARY AND CONCLUSIONS

Tuberculin testing of grade school children about once in 10 years since 1926 served as an accurate measure of effectiveness of the general tuberculosis control program and provided much other valuable information about this disease. Response on the part of the children improved from decade to decade and reached 98.7% in 1954. This excellent response was in part due to schools attempting to qualify for certification by the American School Health Association. Of the 24 schools participating, 23 were certified. In 1926, of the children tested, 47.3% reacted to tuberculin; in 1936, 18.9; in 1944, 7.7; and in 1954, 3.9. During each of these intervals the general tuberculosis control program in the area was intensified. To prevent dissemination of tubercle bacilli, case-finding techniques were improved. Sanatorium facilities became adequate, and tuberculosis was practically eradicated from the cattle herds. In 1954, of the 432 personnel members of these schools 425 (98.4%) responded, of whom 199 (46.8%) reacted to tuberculin. Since the tuberculin reaction indicates the presence of at least microscopic lesions, 455 children and 199 personnel members were found with such lesions. In the strict sense of the word they had cases of tuberculosis.

Tuberculous infection, lesion, illness, and death are one and the same in different stages of the evolution of tuberculosis. The ill and the dying once had only microscopic lesions. All could have been found by the tuberculin test while the lesions were microscopic. Periodic examination of persons who have no evidence of tuberculosis except the tuberculin reaction is the solution of the problem of the high percentage of cases of advanced disease found on first examination. In most cases chronic pulmonary tuberculosis evolves slowly and can be diagnosed while still in the minimal stage before it has caused symptoms and usually before it is contagious. The best place to start is in childhood. All are born free from tubercle bacilli. Periodic testing with tuberculin will detect infections soon after they occur with uncanny accuracy. Periodic examination of those who become reactors will detect the clinical lesions that evolve when they are most treatable.

---

[17] Waring, J. J.: The Current Treatment of Pulmonary Tuberculosis, Dis. Chest 25:361, 1954.

Tuberculin testing of children and seeking the sources of infections of the reactors are excellent epidemiological procedures. Demonstrations are on record in which many times more clinical cases have been found by this method than by mass x-ray surveys. The value of this procedure decreases where communities are periodically combed and clinical cases are removed or adequately treated. This has been demonstrated in the areas where this particular study has been conducted. In the 1920's and early 1930's tracing to the source of an infected child was a frequent occurrence. By 1954 unknown or unsuspected contagious cases had become relatively rare. Apparently most of the sources of infected children had previously been managed. However, the infections in the children remain and must be dealt with accordingly. In this area the tuberculin test has become the master key to the tuberculosis problem. It detects tuberculosis earlier in the human body than any other procedure. It accurately measures the effectiveness of a tuberculosis program. It determines the magnitude of the tuberculosis problem in a given area. It is an excellent epidemiological agent. It promises to tell the physician when to start treatment that may destroy all tubercle bacilli, and it may be our only index for discontinuance of treatment.

1316 Mayo Memorial Bldg. (14) (Dr. Myers).

Cortisone, ACTH and Infection.—Several representative species of virus are among the infectious agents whose capacity to infect is greatly enhanced by cortisone; there is reason to believe that the human organism is host to a great variety of viruses whose identities have not yet been determined and whose long-range injurious effects have not been gauged. It has been shown that malignant human neoplasms, which cannot be transplanted into normal animals, become able to grow without restraint in cortisone-treated animals. Neoplasms which are ordinarily not transmissible in certain species become easily transmissible with the aid of cortisone, and the induction of widespread metastasis with tumors which normally remain localized has been observed. It has even been reported that the growth of tumors induced by carcinogens is augmented by cortisone. It has been shown, furthermore . . . that certain bacterial toxins produce, in cortisone-treated animals, necrotizing lesions of the blood vessels and kidneys which do not occur in normal animals. Experimental streptococcal infections which have remained dormant and hidden for long periods of time have been reactivated to produce lethal septicemia, and similar results have been observed with other types of infection. Mental disturbances, which closely simulate the most malignant forms of mental disease, have occurred as a complication of therapy, and these are especially alarming when they happen, as they have, in young children. It is difficult to be sanguine about drugs with such side-effects as these, and it is not enough to say that some of the reactions are transitory or reversible, or that they do not occur very often. . . . The clinical use of these hormones should not be extended beyond the areas in which it can be predicted that they may save or prolong life, or relieve intractable suffering. This is especially to be emphasized, I believe, for the infectious diseases, in which something of a vogue for the use of cortisone and ACTH as "adjuncts" of therapy is discernible on the horizon.—L. Thomas, M.D., Cortisone, ACTH and Infection, *Bulletin of the New York Academy of Medicine,* July, 1955.

CLINICAL NOTES

POLYCYTHEMIA WITH FIBROIDS

Herbert W. Engel, M.D.
and
Karl Singer, M.D., Chicago

In 1953, Thomson and Marson[1] described a case with fibromyomas of the uterus associated with polycythemia in which, after hysterectomy and bilateral salpingo-oophorectomy, the polycythemia rapidly disappeared. Initially, this patient had a red blood cell count of 7,600,000 per cubic millimeter, a hemoglobin level of 140 gm. per 100 cc., and a total blood volume of 7,286 cc. (Evans blue technique). After surgery, a normal hemoglobin level and red blood cell count became established and were maintained for the next 22 months. A similar observation is reported here to draw attention to this peculiar syndrome.

REPORT OF CASE

A 39-year-old married Negro housewife was first seen in the outpatient clinic on Feb. 20, 1953 with the chief complaint of severe headaches of many years' duration and blurring of vision. At that time, it was discovered that the patient's uterus was irregularly enlarged to the size of a 10 week pregnancy. Her hemoglobin level was 21.4 gm. per 100 cc., with a red blood cell count of 6,800,000 per cubic millimeter and hematocrit (Wintrobe) of 61%. The white blood cell and platelet counts were within normal limits. On Dec. 4, 1953, the patient was admitted to Michael Reese Hospital with complaints of increasing pelvic pressure. Her history included hemorrhoidectomy in 1936 and ectopic pregnancy in 1942. Her menstrual history revealed no abnormalities. Profuse sweating and bluish palms and soles had been noted for many years and more recently also paresthesias of the fingers. No itching after bathing had been observed.[2]

On physical examination, the retinal vessels were normal. Lips and oral mucous membranes appeared cyanotic. No lymphadenopathy was present. The cardiovascular system was without abnormality. The tip of the spleen was palpated 2 cm. below the costal margin. The liver was not enlarged. A mass was felt in the lower abdomen arising out of the pelvis and extending toward the umbilicus. On vaginal examination, this mass was identified as the uterus, was movable, and deviated to the right. It contained multiple, subserous nodules. The adnexa appeared to be normal.

Laboratory Data.—Results of the routine hematological data are found in the table. The hemoglobin level was 19.8 gm. per 100 cc., the red blood cell count was 6 million per cubic millimeter, hematocrit 59%, color index 1.0, mean corpuscular volume 98 cubic microns, sedimentation rate 0, platelets 700,000 per cubic millimeter (normal 300,000 to 700,000), white blood cell count 6,700 per cubic millimeter, sickling test negative. Reticulocytes were 1.1%, prothrombin time (one-stage) 12 seconds, clotting time (Lee-White) 9 minutes. Blood volume (Evans blue technique with correction factor 0.86[3]) was 5,000 cc. (96 cc. per kilogram), plasma volume 2,300 cc. (44 cc. per kilogram), and red blood cell mass 2,700 cc. (52 cc. per kilo-

gram). Examination of the sternal marrow revealed only a mild erythrocytic hyperplasia. Urinalysis was normal. All blood chemistry determinations, including fasting blood sugar level, serum urea nitrogen, uric acid, and liver function tests, were within normal limits. Electrocardiographic, gastrointestinal, and chest x-ray studies were negative. Laparotomy was performed on Dec. 9, 1953, by Dr. M. K. Levin. Multiple, large, uterine fibroids were found, and a total hysterectomy and bilateral salpingo-oophorectomy were performed. Bleeding at surgery was minimal, and hemostasis was effective. The patient's postoperative course was uneventful. Following discharge from the hospital on Dec. 29, the patient's hemoglobin level varied between 12.1 and 13.4 gm. per 100 cc. with hematocrit varying between 40 and 42%. A blood volume determination a month after surgery revealed a total blood volume of 3,427 cc. (66 cc. per kilogram), plasma volume of 2,125 cc. (41 cc. per kilogram), and a red blood cell mass of 1,298 cc. (25 cc. per kilogram). Six months postoperatively, the patient's hemoglobin level was 12.9 gm. per 100 cc., red blood cell count 4,300,000 per cubic millimeter, hematocrit 39%, white blood cell count 7,700 per cubic millimeter with a normal differential count, and platelets 361,000 per cubic millimeter. A blood volume study performed at this time showed a total blood volume of 3,340 cc. (75 cc. per kilogram), plasma volume of 2,575 cc. (50 cc. per kilogram), and red blood cell mass of 1,365 cc. (25 cc. per kilogram). When the patient was last seen (i. e., six months postoperatively), she felt well and was completely asymptomatic. Her headaches and the profuse sweating had disappeared, and the polycythemia had not recurred.

SUMMARY

This case is the second instance of the simultaneous occurrence of polycythemia and uterine fibroids. The hematological abnormalities (high hemoglobin level and red blood cell count and increased red blood cell mass) were completely alleviated by total hysterectomy and bilateral salpingo-oophorectomy. No explanation can be offered for these phenomena that are, however, deemed of sufficient interest to alert the profession into considering such an interrelationship.

29th Street and Ellis Avenue (16) (Dr. Singer).

Arterenol and Migraine.—Arterenol, an agent with almost pure vasoconstrictor and minimal metabolic effects, has been shown to terminate migraine headache promptly, and to reverse evidence of increased tissue vulnerability more rapidly than occurs spontaneously. Observations herein noted suggest that the constricting effect on relatively larger vessels and on arterioles and metarterioles terminates headache and raises deep-pain thresholds. The latter process is presumably effected by drawing a pain-threshold-lowering substance out of tissue and back into the blood.—A. M. Ostfeld, M.D., and H. G. Wolff, M.D., Arterenol (Norepinephrine) and Vascular Headache of the Migraine Type, *A. M. A. Archives of Neurology and Psychiatry,* August, 1955.

FEASIBILITY OF SKIN TESTING FOR PENICILLIN SENSITIVITY

A STUDY OF ONE THOUSAND CASES

Lieut. Col. Arthur J. Berger
and
Capt. Bruno Eisen, (MC), U. S. Army

Many authors have stated that skin tests would determine whether penicillin can cause either anaphylactic or delayed reactions. Before the introduction of antibiotics, including the sulfonamides, many individuals did show sensitivity to different drugs, such as quinine, coal tars, aspirin, and iodides. According to Landsteiner, these drugs were considered haptens and caused a reaction by combination with the plasma proteins. During these times many different methods of testing were tried to determine these sensitivities and were found useless except for the method of trial and error. Since the advent of antibiotics and the increase in sensitivity reactions, this has become a more serious problem. Luckily, most of these reactions were of the delayed type that, although annoying and troublesome, had almost no mortality. Recently, however, up to 40 cases of true anaphylactic shock from the use of penicillin have been reported by different authors, with a high mortality rate.

Until recently, we expected true anaphylactic shock in animals. In the guinea pig the reaction occurs in the bronchial musculature, producing a tetanic contraction that finally causes death by asphyxia. The shock organ in the rabbit is the musculature of the pulmonary artery, and death occurs by complete mechanical interruption of the blood circulation in the arterioles of the lungs. In the dog, the liver is the important shock organ, and death occurs by the collection of blood in the liver, causing hepatic obstruction of circulation. The single prominent feature in all species of animals is the effect on nonstriated muscle. In man, however, the shock organ may vary, not only in different individuals but even in the same individual in response to a single antigen, e. g., the nose, bronchial mucosa, and skin. Symptoms are more often due to edema and rarely, if ever, to contracture of smooth muscle.

From the Department of Medicine, Brooke Army Hospital, Fort Sam Houston, Texas.

In the recent series of deaths and severe anaphylactic shock within minutes of the injection, the patient would become clammy, pulseless, with a marked lowering of blood pressure, and unconscious. Unless stringent measures were instituted, death would ensue. This is in marked contrast to the delayed type reaction, which occurs up to three or four weeks following the injection and consists of many different types. The commonest type is massive generalized urticaria, which at times becomes exfoliative and bullous and even purpuric. Other symptoms are extreme itching, with massive edema usually of the extremities, angioneurotic edema of the face, nausea, malaise, anorexia, laryngeal edema, and possibly spasm. This type of reaction responds well to therapy.

This study was started to show whether testing by any method could determine and prevent these occurrences. The study was carried out in a large Army general hospital. Because the predominant type of penicillin used was procaine penicillin, tests were performed with this agent. The study was carried out by the allergy and immunology section and three groups of patients were used from both the inpatients and the outpatients of the hospital.

TYPES OF PATIENTS

Allergic Individuals.—The group of allergic persons included patients in the average run of all cases referred to the allergy section, so that it can be surmised that most of these patients had an allergic diatheses. Also included were all patients undergoing desensitization therapy at the clinic.

Nonallergic Individuals.—The second group included patients from different wards whether they were receiving penicillin or not. Patients were included from general surgery, orthopedics, general medicine, gynecology and obstetrics, as well as other services, so that the majority could be considered not allergic.

Penicillin-Sensitive Individuals.—The group of penicillin-sensitive persons included some patients in an actual exacerbation of a delayed penicillin reaction. The group included patients with both remote and recent reactions.

METHOD AND MATERIALS

Scratch Test.—Scratch and control tests, with the use of procaine penicillin in dilution, were done and observed in 20 minutes. With appearance of any redness or a wheal, the test result was considered positive and further intradermal testing was not done.

Intradermal Test.—In the second type of test 0.02 cc. of the dilution was injected intradermally, and the result was read in 20 minutes and again in 48 hours. This also was controlled and read as negative or equivocal, 1+, 2+, 3+, or 4+.

Patch Test.—In the patch test a small amount was placed on the dry clean skin and covered with a patch and the reaction was read in 48 hours. This type of test was also controlled and read in the same manner as in the intradermal testing. Passive transfer tests were not done because it would not be feasible in the infinite number of penicillin injections given throughout the country to perform this test.

Dilution Used and Results.—The testing was first started with procaine penicillin in dilution of 5,000 units per cubic centimeter. Because of the minute number of reactions, dilutions were increased to 17,500 units per cubic centimeter and later to 37,500 units per cubic centimeter. The majority of the patients were tested with the stronger dilution in scratch, intradermal, and patch testings. In 1,000 patients given penicillin, there were 24 positive reactions and 976 completely negative reactions. In the 24 positive reactions there was absolutely no relationship to the three groups tested. In fact, most of them occurred in the second group of patients without an allergic diathesis. Of the 24 positive reactions, 5 were suggestive, 15 were 1+, 3 were 2+, and one included anaphylactic shock. The following cases demonstrate some unusual results.

REPORT OF CASES

Case 1.—A 24-year-old Air Force nurse being treated in th hospital for pulmonary tuberculosis had a history of a penicillin reaction several years before. Results of patch and scratc tests were negative; however, on the intradermal test with 1,00 units per cubic centimeter of procaine penicillin, the patie went into complete anaphylactic shock within two minutes. Sh became cyanosed, pulseless, clammy, and nauseated and had complete vascular collapse. Levarterenol (Levophed) in 1,00 cc. of saline solution intravenously helped bring the patie out of collapse in one and one-half hours. There was erythematous eruption of any kind. To make sure we were n dealing with hysteria in this case, three days later we ask the patient if we could do another test with a weaker dilutio of penicillin to determine her threshold of tolerance. She agre to another test but instead was given an intradermal injectio of distilled water; no reaction whatever occurred. She was al tested for procaine sensitivity with negative results.

Case 2.—A 73-year-old retired officer who came for evalu tion from the dental clinic before extraction of a tooth wi associated abscess was given penicillin, 600,000 units, and minutes later suddenly fainted and was found lying on t floor. He was noted to be rather pale and perspiring profusel The peripheral pulse was almost impossible to ascertain b cause of rapid rate and distant heart sounds. The blood pre sure was unobtainable. The patient was given 0.2 cc. of 1:2,6 epinephrine intramuscularly and 5% dextrose in saline sol tion. When he became rational, he complained of generaliz itching. An erythematous flush was noted over the upper anteri trunk. On further questioning, as soon as it was feasible, was found that the patient had had sensitivity reaction to pe cillin in the past. When tested by us at a later date, complete negative results were obtained for scratch, patch, and int dermal tests.

Case 3.—A young physician was given penicillin in the eme gency room because of an oral infection. He had a mild an phylactic shock and experienced dizziness, nausea, and feelin of faintness within two minutes of the injection. Epinephri was given and this reaction was cleared. Results of testing all three methods were completely negative.

Case 4.—A 62-year-old man was being treated at the ho pital for bronchopneumonia. He received procaine penicilli 300,000 units three times daily, for four days. Two weeks lat he developed massive generalized urticaria, edema of ank joints and wrists, severe itching, and nausea. Patient respond to the usual therapy, including administration of corticotrop (ACTH) intravenously. Five weeks later completely negati results of scratch, patch, and intradermal tests were obtained.

Case 5.—A 33-year-old male received four daily injectio of procaine penicillin, 300,000 units each, prophylactically f a minor surgical procedure. On the day of the last injectio he developed generalized urticaria with severe itching. This wa cleared quickly by use of antihistaminics and by stopping a ministration of antibiotics. One week later, results of scratc patch, and intradermal tests were completely negative.

Case 6.—A 30-year-old female came to the dental clinic fo extraction of an infected tooth root. One year previously, sh had had a delayed type of reaction to penicillin. She had rhe matic heart disease. She was given 500,000 units of penicillin G by mouth three times daily for two days and developed generalized pruritus, nausea, malaise, and some dysphagia but no actual skin rash. All symptoms cleared after administration of antibiotics was stopped. Ten days later results of scratch, patch, and intradermal tests were completely negative.

Case 7.—An Air Force nurse, 24 years of age, being treated for pulmonary tuberculosis, had received numerous courses of penicillin therapy previously without complications. She was then receiving streptomycin and isoniazid (Ditubin) daily. The patient showed a reaction to penicillin in 48 hours by intradermal testing. Results of scratch and patch tests were negative.

COMMENT

In the 1,000 cases studied, we feel we have proved that testing is not a reliable way to determine penicillin sensitivity. The fact that many authors give this impression tends to give the practitioner an erroneous confidence in these tests. We are of the opinion that other means must be taken to try to protect the patient. With almost all the population today having been exposed to penicillin in some form or other, we can surmise that anyone is subject to reaction, either immediate or delayed. The indiscriminate use of antibiotic troches, eye drops, ear drops, inhalants, or unguents or the giving of antibiotics for minor complaints tend to sensitize the patient and produce a fertile field for a reaction. In using a combination of penicillin and procaine, we feel we are doubling our chances of reactions, as it is well known that the "caine" products can also produce reactions. It has been noted that all the anaphylactic reactions have occurred in adults. There was one report in the literature of a death in a child from anaphylactic shock but the discussion was very indefinite. Even delayed reactions in children are very rare. Allergists know that children can take much larger doses than adults of pollen in desensitization without getting reactions either locally or constitutionally.

It has been suggested that patients showing delayed reactions be densensitized to penicillin. Sterling[1] did this in small doses in four cases. If this were done, it would take months to build up a high enough tolerance to take an average dose and even then, our use of the desensitizing doses could cause a reaction. We do not believe this is feasible. The use of antihistamines with the penicillin may tend to diminish or abort the delayed manifestations, but we do not feel it would be of any use in preventing the anaphylactic reaction. Wofford[2] believes that an anaphylactic reaction can be caused by penicillin inadvertently being given intravenously. In studying the case reports, no support for this view was noted. Reactions can occur by absorption from the reticular tissue or even from the unbroken skin.

SUMMARY AND CONCLUSIONS

This study demonstrates that skin tests cannot be depended on to determine penicillin sensitivity. To safeguard patients, the following points are of value. Antibiotics should be used only when indicated. If there is a history of previous exacerbation to penicillin, some other antibiotic should be used, if applicable. A preparation for oral use should be used whenever feasible. Care should always be taken if patient has an allergic diathesis. When penicillin is given intramuscularly, it should be given on the lateral aspect of the arm, low enough so that a tourniquet can be applied if necessary, but not so low as to risk radial nerve injury. Patients should always be watched for at least 20 minutes following an injection. If an immediate reaction occurs, a tourniquet should be applied between the site of injection and the heart. Small doses of epinephrine (1:1,000), 0.03 cc. to 0.05 cc., should be given at the site of injection. The patient must have an open air way and sufficient oxygen. Arterenol (Nor-Adrenaline), a pressor substance, 4 mg. in 1,000 cc. of saline solution, should be given intravenously very slowly; this is of distinct value. Dihydrocortisone given intravenously may be lifesaving.

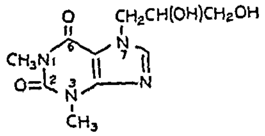
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

R. T. Stormont, M.D., *Secretary.*

Hyphylline.—$C_{10}H_{14}N_4O_4$.—*M.W.* 254.25.—7-(2,3-Dihydroxypropyl)theophylline.—The structural formula of hyphylline may be represented as follows:



Actions and Uses.—Hyphylline, a neutral derivative of theophylline, is stable in gastric juice. Although hyphylline can be administered orally in more effective doses than most theophylline compounds (such as aminophylline), it has not been shown to be superior in this respect to theophylline-sodium glycinate. It exhibits the characteristic peripheral vasodilator and bronchodilator actions of other theophylline compounds, and, in contrast to those that are poorly tolerated by the stomach, it can be expected to be effective orally in the treatment of bronchial asthma, paroxysmal cardiac dyspnea, and Cheyne-Stokes respiration. Hyphylline also produces the typical diuretic and myocardial stimulant effects of theophylline compounds, which are useful in the management of edema secondary to congestive heart failure. Its use in coronary disease or angina pectoris is not recommended until it can be demonstrated that increased coronary blood flow precedes rather than follows myocardial stimulation.

The toxicity of hyphylline in mice is considerably less than that of aminophylline; this difference has not been demonstrated in man, except that it tends to produce less nausea, clinically, when given orally, because it produces less gastric irritation than other theophylline compounds. Large doses of hyphylline, like those of other xanthines, may be associated with unpleasant symptoms of central nervous system stimulation.

Dosage.—Hyphylline is administered orally; for adults, an average dosage is 0.2 gm. three times daily. Smaller oral doses may be adequate to produce a diuretic effect and stimulation of cardiac muscle in congestive heart failure. Larger doses may be required for the control of bronchial asthma, paroxysmal cardiac dyspnea, and Cheyne-Stokes respiration. The dosage should be individualized in accordance with the desired effect and the patient's tolerance to the drug. When oral therapy fails, injection of more soluble theophylline compounds such as aminophylline may be indicated.

Paul Maney Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of hyphylline.

Lututrin.—Lututrin is a uterine relaxing factor obtained from the corpus luteum of sow ovaries by a process of salting out followed by dialysis. It is a water-soluble protein or polypeptide. It is assayed biologically.

Actions and Uses.—Lututrin produces a potent relaxant effect on the guinea pig uterus. Its constitution is somewhat similar to relaxin (Hisaw), a term used to designate a luteal hormone that produces relaxation of the symphysis pubis in the guinea pig; however, lututrin, as assayed primarily for uterine relaxant effect, exhibits little uniformity in relaxin activity. The uterine relaxing factor is not destroyed in the stomach, since the active principle appears in the blood serum within 30 minutes after oral administration.

Lututrin is useful in the treatment of functional dysmenorrhea. In a considerable proportion of patients it relieves to varying degrees the entire symptom complex of that disorder, but is not effective in those women with major psychosomatic difficulties or pelvic anatomic abnormalities. Its effectiveness is enhanced by early administration, ideally the day prior to the onset of menstruation, but certainly before menstrual cramping becomes severe or nausea occurs. Evidence is inadequate to justify its earlier use for the relief of premenstrual tension or for the treatment of threatened or habitual abortion and other conditions involving hypercontractility of the uterus.

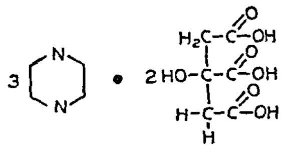
Lututrin produces no sedative action, but large doses have been followed by some drowsiness. No other side-effects have been observed with moderate doses.

Dosage.—Lututrin is administered orally. Dosage is expressed in terms of units of activity on the guinea pig uterus. A unit is defined as "the minimal amount of substance which, when injected intravenously into the estrogenized virgin guinea pig, effects a 90% reduction in the height of spontaneous contractions for a period of at least 10 minutes."

For dysmenorrhea the usual effective dosage ranges from 2,000 to 4,000 units initially, preferably before onset of severe symptoms, followed by 2,000 to 3,000 units every 3 or 4 hours as required. Individual response varies, and doses as high as 10,000 units have been employed without untoward effects.

Hynson, Westcott & Dunning, Inc., cooperated by furnishing scientific data to aid in the evaluation of lututrin.

Piperazine Citrate. — $3C_4H_{10}N_2.2C_6H_6O_7$. — M.W 642.68.—The structural formula of piperazine citrat may be represented as follows:

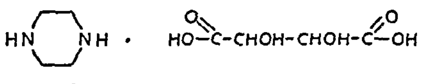


Actions and Uses.—Piperazine citrate is useful as an anthelmintic for the treatment of infections caused by pinworms (Enterobius vermicularis, Oxyuris vermicularis) and roundworms (Ascaris lumbricoides). The drug is relatively nontoxic to humans and usually produces no side-effects when administered in anthelmintic doses. The ingestion of excessively large amounts may produce urticaria or vomiting, blurred vision, and general muscular weakness, which disappear when the drug is discontinued. Excessively prolonged or repeated treatment should be avoided.

Dosage.—Piperazine citrate is administered orally. The dosage is expressed in terms of the hydrous base, piperazine hexahydrate. For children and adults the daily dose may be calculated on the basis of 50 mg. per kilogram (22.7 mg. per pound) of body weight, but this should be limited to not more than 2 gm. daily per patient. The calculated total daily dosage usually is divided into two equal doses administered morning and night. For pinworms, treatment is administered either as a single course for 14 days, or for 7 days followed by a rest period of one week, and a second course for 7 days. For ascariasis, a single course of 5 to 7 days usually is adequate. Appropriate precautions should be taken to prevent reinfection, especially in the treatment of pinworms.

The Blue Line Chemical Company and Burroughs Wellcome & Company, Inc., cooperated by furnishing scientific data to aid in the evaluation of piperazine citrate.

Piperazine Tartrate. — $C_4H_{10}N_2.C_4H_6O_6$. — M.W. 236.23.—The structural formula of piperazine tartrate may be represented as follows:



Actions and Uses.—Piperazine tartrate is used for the same purposes as other salts of the base. See the monograph on piperazine citrate.

Dosage.—Piperazine tartrate is administered orally and, like other salts of the base, the dosage is expressed in terms of the base, piperazine hexahydrate.

Lincoln Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of piperazine tartrate.

Poliomyelitis Immune Globulin (Human).—*Poliomyelitis immune globulin (human* is a sterile solution of globulins that contains those antibodies normally present in adult human blood. Each lot is derived from an original plasma or serum pool that represents at least 1,000 individuals and is processed to contain 165 mg. (± 15 mg.) of globulin per cubic centimeter. It is standardized for its content of poliomyelitis antibodies in compliance with the requirements of the National Institutes of Health, of the United States Public Health Service, inluding the release of each lot individually before its istribution.

Actions and Uses.—Poliomyelitis immune globulin human) is a passive immunologic agent that contains gnificant concentrations of antibodies useful for the ttenuation or prevention of poliomyelitis, measles, and ifectious (epidemic) hepatitis. Significant but tempo-ry protection against the development of paralytic oliomyelitis has been produced from the second through ie fifth week following injection; but the likelihood of ecuring protection against paralytic poliomyelitis by ie use of the globulin is much less than the likelihood of ecuring protection against measles or infectious (epi-emic) hepatitis by the same means. The preparation is quivalent in usefulness to immune serum globulin (hu-ian) for the prevention or modification of measles when ijected within the first 6 days, but not beyond the 10th lay, following initial exposure. It also prevents or ttenuates infectious (epidemic) hepatitis when in-ected during the incubation period; it apparently con-ers passive immunity to that infection for 6 to 8 weeks.

Poliomyelitis immune globulin (human) is regarded s being free from the virus of serum hepatitis. Sensitiza-on to repeated injections is extremely rare. Injections ccasionally may be followed by local tenderness and tiffness of muscles persisting for several hours. Care hould be exercised to avoid accidental intravenous ad-inistration.

Dosage.—Poliomyelitis immune globulin (human) is dministered only by intramuscular injection, prefer-bly in the buttock. *Careful technique is essential to void accidental intravenous injection.*

For protection against paralytic poliomyelitis, the verage dose to be injected is calculated on the basis of .14 cc. per pound (0.31 cc. per kilogram) of body veight. This dose may be repeated in 6 weeks if con-inued protection is desirable.

For the modification of measles, the dose is calculated n the basis of 0.02 to 0.0246 cc. per pound (0.044 to .055 cc. per kilogram) of body weight; for complete revention, at least 0.10 cc. per pound (0.22 cc. per ilogram) should be employed. Either dose preferably hould be given within 6 days after initial exposure.

For prevention or attenuation of infectious (epi-emic) hepatitis, the suggested dose is 0.02 cc. per ound (0.044 cc. per kilogram) of body weight in chil-lren or adults; this dose should be repeated in 3 weeks f longer protection is desired.

Cutter Laboratories and Sharp & Dohme, Division of Merck & Co., nc., cooperated by furnishing scientific data to aid in the evaluation of oliomyelitis immune globulin (human).

Vibesate.—A mixture containing 9.3% polvinate and .1% malrosinol in a mixture of organic solvents and a ropellant.

Actions and Uses.—Vibesate is a modified polyvinyl lastic that forms a rapidly drying, transparent, pliable, nd occlusive film when applied topically as a liquid pray containing a suitable volatile solvent and gaseous ropellant. This film is useful as a surgical dressing, omewhat resembling that of flexible collodion. Vibesate ilm is semipermeable to water vapor, permitting the es-ape of moisture when applied to the skin. It retards the escape of fluids and electrolytes from injured areas, but it does not prevent such loss from the tissues. The transparency of the plastic film permits detection of evidence of infection in superficial wounds, and it can be peeled off readily when drainage and local anti-infective therapy become necessary.

Vibesate is useful as an occlusive surgical dressing for burns as well as for operative wounds and other surface lesions, particularly when the use of gauze or other fabricated dressings is undesirable or inconvenient. Like other local applications for burns, the film may relieve pain because of the exclusion of air. It is better adapted for dressing burns that are to be treated by the exposure method than for those treated by the older compression gauze technique. The plastic film also may replace gauze or other fabrics as a definitive surgical dressing for various closed operative incisions that do not require protective padding or the prolonged use of drains. In the open reduction of fractures it permits the application of skin-tight plaster casts. The film also is suitable for covering certain skin eruptions, including macerated excoriations, decubitus and traumatic ulcers, and abrasions. The film usually remains intact for the period of normal healing unless the area involved is subject to considerable motion or stress; removal and reapplication may be required to maintain occlusion or to permit proper care of contaminated wounds. There is, of course, especial danger if anerobic organisms proliferate.

Vibesate is considered to be a relatively inert plastic and has not been reported to cause toxic, sensitivity, or allergic reactions or to interfere with healing. The volatile ethyl acetate-acetone solvent employed as a vehicle has not produced significant irritation, but transitory smarting or stinging occurs during application to sensitive surfaces. For this reason contact with the eyes or other delicate mucous membranes should be avoided. The gaseous propellant employed, a fluoro-chloro hydrocarbon, ordinarily does not come in close contact with the tissues; however, the volatile solvent and propellant are hazardous from the standpoint of accidental inhalation and flammability. Care should be taken during application to avoid inhalation of the vapors or their use near an open flame. The container should not be punctured close to an open flame or thrown into a fire.

Dosage.—Vibesate is applied topically by spraying the area of the wound or lesion to be dressed. The affected area should first be cleansed thoroughly and allowed to dry. The spray usually should be applied back and forth, parallel to the injured surface at a distance of not less than 15 cm. (6 in.), preferably at about 30 cm. The spraying should include a suitable border of normal skin to afford proper anchorage. The film is allowed to dry for at least 30 seconds after each application and the spray repeated two or three times as may be required to obtain a tough, flexible film with a final thickness of 0.05 to 0.08 mm. To insure ease of removal the film thickness should not be less than the minimum. The film may be applied directly over sutured wounds, and it may be peeled off when thoroughly dry and reapplied whenever indicated.

Aeroplast Corporation cooperated by furnishing scientific data to aid in the evaluation of vibesate.

USE OF CORTISONE IN RHEUMATIC CARDITIS WITH CONGESTIVE HEART FAILURE

The place of cortisone and related hormones in the treatment of acute rheumatic fever, including acute rheumatic carditis, remains controversial. Some persons consider these hormones to exert no more effect than salicylates in such cases.[1] However, a considerable number of experienced clinicians hold that the use of cortisone-like hormones is the most effective measure presently available for suppression of the rheumatic inflammatory reaction in the heart and hence is indicated in the treatment of acute rheumatic fever.[2]

Congestive heart failure in rheumatic fever can be attributed to one or more of at least three factors: (1) reversible weakening of the myocardium from the rheumatic inflammatory process (rheumatic myocarditis), (2) excess strain on the heart muscle from damaged valves, and (3) irreversible changes in cardiac muscle secondary to rheumatic inflammation. The cortisone-like hormones are considered to relieve congestive failure in active rheumatic carditis by means of their suppressive effect on the first of these factors: the active rheumatic myocarditis.

Initially, there was some hesitation in the use of co tisone against acute rheumatic carditis with congesti failure, since it was theorized that the salt-retaining effe of cortisone might lead to an increase in the degree failure. However, experience has shown that the co gestive heart failure has abated, in the majority of cas after such treatment. In only a few cases has the co gestive heart failure been increased, and in most of the the initial increase subsequently has been followed an abatement or disappearance of congestive heart fa ure, presumably when the antirheumatic effect of hormones has had time to take effect. The use of newer cortisone-like hormones with lessened salt-reta ing tendencies, such as prednisone and prednisolo should prove of value from the standpoint of avoidi an initial aggravation of congestive failure arising fr retention of salt. To produce an equivalent antirh matic effect, doses of prednisone or prednisolone sho be about one-fourth the dose of cortisone.

In the treatment of acute rheumatic fever some[3] n advocate the use of 300 mg. of cortisone daily for weeks, after which time the dose is gradually lesse and finally discontinued over a period of two to th weeks. With such doses of cortisone the use of a containing 50 mg. or less of sodium daily and sup mentary potassium is recommended. Others[4] h employed initially 200 to 300 mg. of cortisone d (sometimes less for small children), until all signs rheumatic activity have been suppressed (often one two weeks) and thereafter have reduced the dose about 100 to 150 mg. daily for the next four to six we or more; then the dose has been tapered off in anot few weeks, as permitted by the patient's response. M agree that no one routine schedule of dosage has been devised that is satisfactory for all patients rather, that the dose must be regulated so that a suffici suppressive amount is given for the duration of the act phase of the disease. Recurrences after treatment flares after reduction of dosage) indicate the need further treatment (or a temporary increase in dosag

In the treatment of rheumatic carditis with congest heart failure the cortisone-like hormones should not considered the sole treatment but, rather, should be p of a complete program that should also include in bed, low-salt diet, penicillin, and, if necessary, uretics, digitalis, and oxygen. The use of salicyla along with the hormones has been suggested by son

MEDICAL NEWS

CALIFORNIA

Annual Postgraduate Assembly.—The ninth annual postgraduate assembly of the San Diego County General Hospital will have as guest speakers, Sept. 21-22, the following physicians: Nelson Paul Anderson, Los Angeles (dermatology), Elmer C. Bartels, Boston (medicine), Willard M. Allen, St. Louis (obstetrics and gynecology), LeRoy Abbot, San Francisco (orthopedics), Merl J. Carson, Los Angeles (pediatrics), Willis J. Potts, Chicago (surgery), and Wyland F. Leadbetter, Boston (urology).

Course on Surgical Techniques.—Designed for the general surgeon to relate anatomy to standard and newer surgical techniques, a course in surgical anatomy will meet Sept. 20-Nov. 22, 7:30-9:30 p. m., on Tuesdays in the second floor lecture room (Room 23-105), University of California Medical Center, Los Angeles, under the auspices of university extension. No textbooks will be required for the course, which is limited to 30 students who are graduates of approved medical schools. Requests for information should be made to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, University of California Medical Center, Los Angeles 24.

Postgraduate Symposium.—The first annual postgraduate symposium will be presented by the medical staff of Herrick Memorial Hospital, Berkeley, Sept. 23, at the Berkeley High School Little Theatre. Members of the Alameda-Contra Costa County Medical Association and all other Bay Area physicians are invited. The sessions will include panel discussions in medicine, surgery, and endocrinology, with the following participants: Drs. Isidore S. Edelman, Morton A. Meyer, Sheldon Margen, and Albert Snell, University of California School of Medicine, San Francisco; Drs. Joseph P. Kriss and Henry P. Brean, Stanford University School of Medicine, San Francisco; and Dr. Francis D. Moore, Harvard Medical School, Boston.

Postgraduate Surgical Programs.—The San Francisco chapter of the American Academy of General Practice will again sponsor a series of postgraduate surgical programs, given by the surgical service of Fort Miley Veterans Administration Hospital in cooperation with the University of California Medical School. The sessions will be held in the auditorium of the Fort Miley VA Hospital, 42nd Avenue and Clement Street in San Francisco, on six Tuesday evenings from 8 to 10 p. m. (from Sept. 20 to Nov. 8, with the exception of Oct. 11 and 18). Twelve hours of educational credit will be given to members of the American Academy of General Practice for attendance. Dr. Louis Brizzolara, chief of surgical service at the hospital, will act as moderator, Dr. Forrest M. Willett, chief of medical service, as coordinator, and Dr. Alexander F. Fraser, president of the San Francisco chapter of the academy, will be chairman.

CONNECTICUT

Children's Tumor Clinic.—A children's tumor clinic has been established at the Yale-New Haven Medical Center under the joint sponsorship of the Yale University School of Medicine and the Grace-New Haven Community Hospital and the Connecticut division of the American Cancer Society. The new clinic will be directed by Dr. David H. Clement, associate clinical professor of pediatrics, and Dr. Alan C. Mermann, clinical instructor in pediatrics. The tumor clinic, designed to work with the family physician on a consultation basis, will supplement or corroborate the physician's diagnosis and will make available to him the services of the entire staff of the medical center.

Course in Infectious Diseases.—Yale University School of Medicine, New Haven, announces a postgraduate course for practicing physicians on "Infectious Diseases: Problems of Clinical Diagnosis and Management." Eight weekly teaching conferences, each consisting of talks by two or more speakers followed by a question-answer period, will be presented from 2:30 to 5 p. m. Thursday afternoons, Sept. 29-Nov. 17, in the Farnam Auditorium, Yale-New Haven Medical Center, 789 Howard Ave. Dr. Robert R. Wagner, assistant professor of medicine, will serve as director for the following program:

Sept. 29, Response to Infection.
Oct. 6, Acute Respiratory Infections.
Oct. 13, Childhood Infections.
Oct. 20, Central Nervous System Infections.
Oct. 27, Enteric and Intra-Abdominal Infections.
Nov. 3, Systemic Infections.
Nov. 10, Genitourinary Infections.
Nov. 17, Rational Basis of Chemotherapy (symposium).

Registration fee and tuition will be $40 for the series; interns and residents may register without charge. Admission will be limited to physicians who have registered in advance.

ILLINOIS

Programs for General Practitioners.—The Illinois Academy of General Practice will present its seventh annual postgraduate program at 8:30 a. m. on six consecutive Wednesdays beginning Oct. 5 at the Illini Union Building, South Chicago Community Hospital, and the Swedish Covenant Hospital. Faculty members from the University of Illinois, Loyola University, Chicago Medical School, Northwestern University, and the University of Chicago will discuss Consultations in Gynecology; Cardiovascular Disease; Common Surgical Conditions; Hematologic Problems in Everyday Practice; and Enigmas in Treatment.

Chicago

Volunteer Medical Company.—A meeting of the Volunteer Medical Company 9-20, U. S. Naval Reserve, will be held at the U. S. Veterans Research Hospital, Room A-302, 333 E. Huron St. (MOhawk 4-6600), at 8:15 p. m. Sept. 20. "Evaluating the 'Risk of Death'" will be presented by Dr. Charles A. Gianasi, assistant medical director, Continental Assurance Company.

William Allen Pusey Lecture.—The ninth William Allen Pusey Memorial Lecture of the Institute of Medicine of Chicago will be presented at a joint meeting of the institute and the Chicago Dermatological Society at the Congress Hotel Sept. 21, 8:15 p. m. Dr. Harvey Blank, associate medical director, Squibb Institute for Medical Research, New Brunswick, N. J., will discuss "Clinical Aspects of Recent Virus Research." Dr. Blank is research associate in dermatology, Columbia University College of Physicians and Surgeons, New York, and associate in dermatology, University of Pennsylvania Graduate School of Medicine, Philadelphia. This open meeting, to which all are welcome, will be preceded by cocktails, 6 p. m., and dinner ($5.50 per plate). Telephone during the meeting, HArrison 7-3800.

Health Lectures at the Museum of Science and Industry.—The 1955 fall lecture series at the Museum of Science and Industry will be conducted on five Sunday afternoons at 3 p. m. beginning Sept. 25. Dr. Elmer Hess, Erie, Pa., President of the American Medical Association, the first speaker, will be introduced by Dr. F. Garm Norbury, Jacksonville, Ill., president of the Illinois State Medical Society, and will have as his subject "The Patient and the Doctor." The series will include:

Willis J. Potts, Chicago, surgeon-in-chief, Children's Memorial Hospital, Oct. 2, Heart of a Child.
Philip Thorek, Chicago, associate professor of surgery, University of Illinois College of Medicine, Oct. 9, Food for Thought About Health.
James W. J. Carpender, Chicago, professor of radiology, University of Chicago, Oct. 16, X-Rays and Radioactive Substances.
Morris Fishbein, Chicago, clinical assistant professor of medicine, University of Illinois College of Medicine (Rush), Oct. 23, Live Longer and Like It.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

INDIANA

Postgraduate Assembly in Endocrinology.—The seventh annual postgraduate assembly of the Endocrine Society in cooperation with the Indiana University School of Medicine will convene at the Indiana University Medical Center, 1100 W. Michigan St., Indianapolis, Sept. 26-Oct. 1. Out-of-state speakers will include:

- Charles W. Lloyd, Syracuse, N. Y., Anterior Pituitary, Anatomy and Present Status of Physiology—Relation to Hypothalamus.
- Roberto F. Escamilla, San Francisco, Hypopituitarism—Dwarfism, Simmonds' Disease, Sheehan's Syndrome, Frœlich's Syndrome.
- Karl E. Paschkis, Philadelphia, Hyperpituitarism—Gigantism and Acromegaly.
- Brown M. Dobyns, Cleveland, Thyroid, Anatomy and Physiology—Relation to Pituitary.
- Rulon W. Rawson, New York, Goiter—Classification and Present Concepts.
- Henry H. Turner, Oklahoma City, Hypothyroidism—In Childhood and in Adults.
- Edward C. Reifenstein Jr., New York, Parathyroids—Anatomy and Physiology.
- Frank L. Engel, Durham, N. C., Hyperparathyroidism.
- Ralph I. Dorfman, Ph.D., Boston, Adrenal Cortex—Anatomy, Chemistry and Physiology.
- Robert B. Greenblatt, Augusta, Ga., Cushing's Disease and Cushing's Syndrome.
- Lawson Wilkins, Baltimore, Adrenogenital Syndrome, Including Congenital Type—Diagnosis and Treatment.
- Edward H. Rynearson, Rochester, Minn., Hyperinsulinism and Spontaneous Hypoglycemia.
- Earl T. Engle, Ph.D., New York, The Testis—Anatomy and Physiology.

LOUISIANA

Dr. Peters Goes to Kansas.—Dr. Lawrence Peters recently joined the faculty of the University of Kansas School of Medicine, Kansas City, as chairman of the department of pharmacology, leaving a similar position in the Tulane University of Louisiana School of Medicine, New Orleans. Dr. Peters received the bachelor of science degree in pharmacy from the University of Saskatchewan, Saskatoon, Canada, in 1938, doctor of philosophy degree in pharmacology in 1942 from University of Minnesota, Minneapolis, and doctor of medicine degree from Western Reserve University School of Medicine, Cleveland, in 1950.

Refresher-Type Courses. — The Louisiana State University School of Medicine, New Orleans, in cooperation with the Louisiana State Medical Society will resume its one-day refresher-type courses in the fall. This year courses will be given not only at the medical school in New Orleans but also at the Confederate Memorial Medical Center in Shreveport and at other centers in the state. The following courses have been scheduled:

- Gastroenterology, New Orleans, Sept. 24 (under the direction of Dr. G. Gordon McHardy).
- Heart Disease, Shreveport, Oct. 26 (under the direction of Dr. Marion D. Hargrove).
- Surgical Diagnosis, Shreveport, Nov. 16 (under the direction of Dr. Paul D. Abramson).

Programs for each course may be obtained by writing Dr. Edgar Hull, associate dean. Suggestions for the subject matter of future courses will be welcome.

MICHIGAN

State Medical Meeting in Grand Rapids.—The 90th annual meeting of the Michigan State Medical Society will convene at the Pantlind Hotel, Grand Rapids, Sept. 26-27 under the presidency of Dr. Robert H. Baker, Pontiac. The house of delegates will hear a panel on undergraduate medical education, with Dr. Jackson E. Livesay, Flint, speaker, as moderator, and Dr. Albert C. Furstenberg, dean, University of Michigan Medical School, Ann Arbor, and G. H. Scott, Ph.D., dean, Wayne University College of Medicine, Detroit, as participants, at a dinner meeting Monday, 6:30 p. m. (this panel was originally scheduled for a luncheon meeting). Wednesday, general practice day, there will be a surgery panel at 9 a. m. in which "Management of Duodenal Ulcer" will be considered. Dr. Stanley O. Hoerr, Cleveland, will serve as chairman and Drs. Russell Best, Omaha, and Ralph Colp, New York, as participants. "Medicolegal Problems in Industrial Surgery" by Dr. Russell S. Fisher, Baltimore, will precede "Malignancy of the Upper Urinary Tract" by William N. Taylor, Columbus, Ohio. The Wednesday afterno program will include:

- Infections in Newborn Infants, Ralph V. Platou, New Orleans.
- Vaginal Discharge, Leon S. McGoogan, Omaha.
- Endometriosis, with Special Reference to Massive Stilbestrol Thera Willard R. Cooke, Galveston, Texas.
- Evolution of Psychiatry as an Integral Part of General Practice, Maur Levine, Cincinnati.

A general (public) meeting has been scheduled for Wednesd 8:30 p. m. The Andrew P. Biddle Lecture, "Forever Sacre will be delivered by Charles L. Anspach, Ph.D., LL.D., Mo Pleasant, Mich., president of Central Michigan College of E cation. The following program will be presented on Thursd

- Anatomical Considerations in Surgery of the Gall Bladder, Barry Anson, Ph.D., Chicago.
- Visual Symptomatology, Hugo L. Bair, Rochester, Minn.
- Ear, Nose and Throat Symptoms Related to General Medical Con tions, James B. Costen, St. Louis.
- Role of the Family Physician in Psychiatric Problems, Francis Braceland, Hartford, Conn.
- Vaginal Delivery After Prior Cesarean Section, Samuel A. Cosgro Jersey City, N. J.
- Indications for Hysterectomy, Richard W. TeLinde, Baltimore.
- Diabetes Mellitus in Children, Waldo E. Nelson, Philadelphia.
- Development of Communicable Disease and Control, Franklin H. T Iowa City.

The Michigan State Medical Society will be host at a cabar style dance and floor show Thursday, 10:30 p. m., for all reg trants and guests. The Friday assembly will open at 9 a. m. w the William Beaumont M.D. Lecture (sponsored by the Michig Foundation for Medical and Health Education, Inc.), "Rece and Important Changes in Treating Colonic and Rectal Car noma," by Dr. Garnet W. Ault, Washington, D. C. The mainder of the day will be devoted to the following presentatio

- Dermatitis of the Hands, Richard L. Sutton Jr., Kansas City, Mo.
- Relationship of Radiation to Surgery in Cancer of the Breast, Har W. Jacox, New York.
- Cutaneous Manifestations of Systemic Disease, Robert R. Kierla Rochester, Minn.
- Role of the Anesthesiologist in Care of Poliomyelitis Patients, Freder H. Van Bergen, Minneapolis.
- New Developments in Treatment of Coronary Occlusion, Arthur Master, New York.
- Causes of Pain in the Chest, Ovid O. Meyer, Madison, Wis.
- Medical Symposium on "The Newer Therapeutic Tools," A. Carl Ernstene and Penn G. Skillern, Cleveland.

The guest speakers will participate in daily discussion conf ences from 12 noon to 1 p. m. in the Black and Silver Room the Civic Auditorium. The woman's auxiliary will meet sim taneously.

MINNESOTA

Dr. Wangensteen Honored.—The Owen H. Wangensteen Sur cal Education Foundation, an organization made up of form residents of Dr. Wangensteen, will honor the 25th anniversa of his appointment as professor of surgery and chief of the d partment of surgery at the University of Minnesota Medic School, Minneapolis, by presenting a scientific program in th Mayo Memorial Auditorium of the University of Minneso Hospitals Sept. 23-24. On the day preceding the meeting the will be an operative clinic on cardiac surgery. The topics f discussion on Friday and Saturday will be "Experimental Su gery," "The Cancer Problem," and "Surgical Problems." public banquet will be held on Friday evening, honoring D Wangensteen. The principal speaker will be Mr. John M. Ru sell, New York, executive director of the John and Mary Markl Foundation. On the succeeding evening there will be a meetin of the Owen H. Wangensteen Surgical Education Foundation.

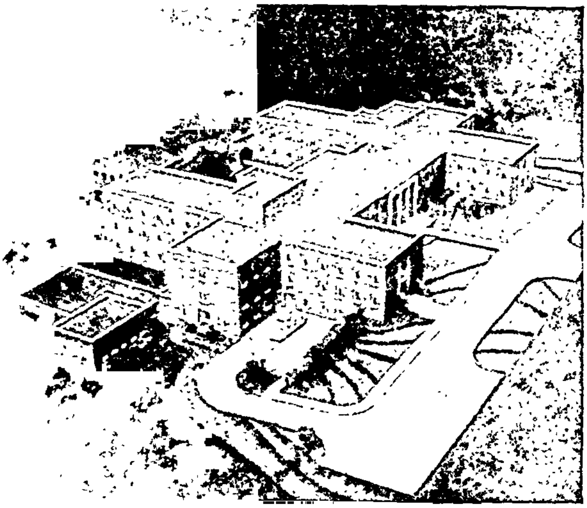
MISSOURI

Mac Cahal Receives Award.—A U. S. Chamber of Commerc committee, headed by the Hon. Sinclair Weeks, Secretary o Commerce, recently presented to Mac F. Cahal, executive secre tary of the American Academy of General Practice, the Dis tinguished Service award, given annually by American Trad Association executives in recognition of exceptionally effectiv public service programs. Mr. Cahal, who has been director o the academy since it was founded eight years ago, formerly was director of the American College of Radiology in Chicago

ersonal.—Dr. Theodore Cooper, intern at the St. Mary's roup of Hospitals of St. Louis University, has been awarded postdoctoral research fellowship in the physiology department f St. Louis University School of Medicine by the U. S. Public ealth Service. His research in the investigation of the re-ctivity of the blood vessels, with respect to various drugs, will e conducted under Albert B. Hertzman, Ph.D., director, de-artment of physiology, and will be aided by a grant from the t. Louis Heart Association. Last June Dr. Cooper received he $500 annual Borden award for the best original work sub-itted by a senior medical student, in which, through research n the action of Adrenalin and related compounds on the blood essels, he developed a technique of measuring the reactivity f the blood vessel, allowing for the initial state of the blood essel before it is subjected to the action of any additional nfluence.——Dr. Dean F. Davies, St. Louis, was recently ppointed research associate of the American Cancer Society. r. Davies was associated with St. Luke's and Missouri Baptist ospitals and the Washington University School of Medicine, vhere he served as assistant professor of biochemistry and ssociate director of the hypertension division of the depart-nent of medicine. His new headquarters are at the American Cancer Society's national office, 521 W. 57th St., New York.

EBRASKA

edication of Psychiatric Institute.—The Nebraska Psychiatric nstitute on the campus of the University of Nebraska College f Medicine in Omaha was recently dedicated at ceremonies in hich the principal speakers were Sen. Roman Hruska, Omaha, nd Dr. Arthur P. Noyes, Norristown, Pa., president, American sychiatric Association. Governor Victor E. Anderson closed he program and presented Dr. Cecil L. Wittson, director of the nstitute, with the key to the building. The institute provides or the teaching and training of psychiatrists, psychologists, sychiatric aides, psychiatric social workers, electroencephalo-raphic technicians, and nurses. It will place emphasis on re-earch and treatment of the mental and emotional problems of hildren and the aged.



Model of Nebraska Psychiatric Institute, University of Nebraska College f Medicine, Omaha.

EW YORK

ociety News.—At its meeting Sept. 20 at Binghamton City ospital Auditorium, the Binghamton Academy of Medicine vill have as speaker Dr. George E. Moore, medical director of he Roswell Park Memorial Institute, Buffalo. His subject will e "Present and Future Programs of the Roswell Park Memorial nstitute."

Hospital Teaching Day.—A teaching day will be held at Roches-er General Hospital Sept. 22. Morning sessions will consist of study of pediatrics through ward walks or choice of the following clinics: (1) Cholografin, (2) fibrinogenopenia, as it relates to premature separation of the placenta, (3) pulmonary function studies in various lung conditions, or (4) ballistocardiography. A panel discussion concerning the use of serums, vaccines, and gamma globulin in the treatment of various infectious diseases of children will be presented in the afternoon. Practical laboratory diagnostic tests, which the practicing physician may use in his office, will be demonstrated by Drs. Milton G. Bohrod and Andrus I. Roodenburg, Rochester. Dr. Waldo E. Nelson, professor of pediatrics, Temple University School of Medicine, Philadelphia, and author of "Textbook of Pediatrics," will discuss "Pediatrics Practice by the Family Physician."

New York City

First Harvey Lecture.—J. C. Eccles, professor of physiology, the Australian National University, Canberra, will deliver the First Harvey Lecture of the 1955-56 series at the New York Academy of Medicine Sept. 22 on Excitatory and Inhibitory Synaptic Action.

Joint Meeting on Medicine and Pharmacy.—A joint program on medicine and pharmacy will be presented at the annual meeting of the Pharmaceutical Council of Greater New York at the Hotel Statler, Sept. 21, 8 p. m. A committee of three physicians appointed by the Coordinating Council of the County Medical Societies of the City of New York cooperated with the committee of the Pharmaceutical Council in arranging the following program on "Radioactive Isotopes in Medicine and Pharmacy":

Solomon Silver, Diagnostic Uses of Radioactive Isotopes.
George Himler, Therapeutic Uses of Radioactive Isotopes.
Paul Numerof, Sc.D., Use of Isotopes in Pharmaceutical Research.

All physicians are cordially invited to attend.

OKLAHOMA

Indian Health Area Office.—Dr. Alonzo F. Brand has been appointed medical officer in charge of the Indian Health Area Office in Oklahoma City, the public health service has announced. Dr. Brand will administer the federal government's expanded program for Indian health in Oklahoma, Kansas, Florida, Mississippi, and North Carolina. About 67,500 Indians living on reservations in these states receive medical care and public health services under the supervision of the Oklahoma City office. Dr. Brand will be responsible for the operation of the eight public health service hospitals for Indians in the area, for the health program in six Indian boarding schools, and for hospital care furnished to Indians through contracts with community hospitals. Dr. Brand was commissioned in the public health service in 1942 and is a career medical officer. He has served with health departments or public health service regional staffs in San Antonio, Texas; New Orleans; Memphis, Tenn.; Richmond, Va.; and San Francisco and has served in Washington, D. C.

PENNSYLVANIA

Society News.—The Pennsylvania Radiological Society recently elected Drs. William T. Rice, Rochester, president; James M. Converse, Williamsport, president-elect; Jesse T. Littleton III, Sayre, first vice-president; John F. Maurer, Greensburg, second vice-president; Walter P. Bitner, Harrisburg, secretary-treasurer; and Carl B. Lechner, Erie, editor.

Philadelphia

Course in Obstetrics and Gynecology for Practitioners.—A 12 week postgraduate course in obstetrics and gynecology for the general practitioner, to be initiated at Hahnemann Medical College and Hospital Sept. 28, will cover prenatal care; toxemias; urologic, psychological, and psychiatric problems; third trimester bleeding; gynecologic back pain; abnormal vaginal bleeding; dysmenorrhea; endometriosis; pelvic cancer; study of the infertile couple; and pediatric and geriatric gynecology. Information about the course, which has been approved for credit by the American Academy of General Practice, may be obtained from Dr. Bruce V. MacFadyen, 230 N. Broad St., Philadelphia 2.

TEXAS

Meeting of General Practitioners.—Guest speakers for the sixth annual scientific assembly of the Texas Academy of General Practice at the Will Rogers Memorial Coliseum Sept. 19-21 will include: Drs. Edwin F. Cave and Laurence L. Robbins, Boston; Drs. William F. Mengert and Philip Thorek, Chicago; Dr. Katherine Dodd, Little Rock, Ark.; Dr. J. Vernon Knight, Nashville, Tenn.; Dr. Louis G. Moench, Salt Lake City; Dr. Carl A. Moyer, St. Louis; Dr. Arthur G. Schoch, Dallas, Texas; and Dr. J. Minott Stickney, Rochester, Minn.

WASHINGTON

Symposium on Cardiovascular Disease.—The seventh annual symposium on heart disease will be presented by the Washington State Heart Association and Washington State Department of Health at the University of Washington School of Medicine, Seattle, Sept. 30 and Oct. 1. The theme will be "Myocardial Infarction" and "Pericarditis." Speakers including Drs. Howard B. Sprague, Boston, Charles E. Kossman, New York, and Jesse E. Edwards, Rochester, Minn., will conduct panel sessions and discuss questions from the audience as well as present scheduled papers, which will include "Conditions Mistaken for Coronary Disease," "Errors in Electrocardiographic Diagnosis," "Employment and Compensation Problems," and "Lesions Simulating Pericarditis." The symposium is the equivalent of nine hours of formal postgraduate training for members of the Academy of General Practice. There will be no registration fee. On Saturday afternoon there will be a meeting of the Washington State Society of Internal Medicine at the medical school auditorium.

GENERAL

Grants for Hematology Research.—The Hematology Research Foundation invites applications for grants-in-aid for hematological research for a period of one year. Nine copies of application must be submitted no later than Nov. 1, 1955, to Hemaology Research Foundation, 64 W. Randolph St., Chicago 1. Application forms are available on request. Awards will be announced by the medical advisory board of the foundation the latter part of November.

Meeting of Medical Writers.—The American Medical Writers' Association will hold its 12th annual meeting at the Hotel Jefferson, St. Louis, Sept. 30. "Clarity in Medical Writing" will be discussed by Dr. Joseph Garland, Boston, and "Do Statistics Clarify or Confuse?" by Alan E. Treloar, Ph.D., Minneapolis. The afternoon session will be on the preparation of medical presentations, with Dr. Dean F. Smiley, Chicago, as moderator. A workshop is scheduled for Oct. 1.

Fake Uniform Salesman Reported.—According to the Alameda-Contra Costa (Calif.) Medical Association, the Topps Garment Manufacturing Company of Rochester, Ind., reports that a salesman claiming to represent their company has been touring the West and taking orders prepaid for uniforms that are not delivered. The company advises that the salesman is not their representative and that orders placed with him are not sent to them. The salesman claims to be a retired Navy man and carries a well-worn uniform catalogue and brief case. He presents Topps Garment Manufacturing Company cards as well as other credentials. He is described as about 50 years old, weighs 250-300 pounds, has an accent, gray hair, and is about 6 ft. 2 in. tall.

Senior Fellowships in Cardiology.—The New York Heart Association this fall will offer three senior fellowships, each for a period of three years and renewable for an additional two years, with annual stipends starting at $6000 and annual increments of $500. These full-time fellowships are available to young men and women under age 35 who have attained a doctorate degree, have demonstrated a competence for research, and who have a definite orientation toward fundamental research in the cardiovascular field. Research programs are to be carried out in recognized institutions within the area of the five boroughs of New York. For further information write the Medical Director, New York Heart Association, Inc., 485
Ave., New York 17. Closing date for applications is Oc
1955.

Catastrophic Accidents.—The Metropolitan Life Insurance
pany reports that, although catastrophic accidents (those k
five or more persons) took nearly 550 lives during the fir
months of this year in the United States, the total is som
smaller than that for the first half of 1954 and is one of the
est on record. Deaths in tornadoes increased appreciably
tornado, crossing five midwestern states on May 25, killed
115 people, 80 of them in Udall, Kan. There was only one
disaster in which 25 or more lives were lost—the Februar
fire in a men's hotel in Chicago in which 29 were killed.
trophes involving dwelling and apartment house fires, mi
aviation, and motor vehicle accidents took substantially
lives during the first half of 1955 than in the similar peri
1954, but the number of deaths in civilian aviation catastr
was somewhat higher.

Rehabilitation Training Program.—The Institute for the
pled and Disabled, New York, announces plans for a s
training program to prepare persons in rehabilitation fo
level positions of coordination and administration in reha
tion centers. The proposed starting date for the seven
course is Dec. 1. Applications received by Oct. 15 will be
preference. Applicants for the course should have had at
three years' experience in some fields of rehabilitation. Tr
will receive a monthly stipend of $250 for the seven
period, in addition to round-trip travel expenses from t
stitute to the places of on-the-job training. All other ex
will be borne by the trainees. Except in cases of unusual q
cation, trainees must be between 30 and 50 years of ag
formation may be obtained from the Director, Institute f
Crippled and Disabled, 400 First Ave., New York 10.

Conference on Hospital Planning.—A Conference on H
Planning will be held Sept. 20, 9-11:30 a. m., in Conv
Hall, Atlantic City, N. J., during the 57th annual convent
the American Hospital Association. All convention regis
are invited to attend the conference, which will be pre
under the auspices of the American Hospital Association C
on Hospital Planning and Plant Operation and joint spons
of the American Association of Hospital Consultant
American Institute of Architects, and the American Assoc
for Hospital Planning. Frank S. Groner, chairman of the
can Hospital Association Council on Hospital Plannin
Plant Operation, will preside. The keynote speaker w
Dr. Leonard A. Scheele, surgeon general of the U. S.
Health Service, Department of Health, Education, and W
Washington, D. C., whose subject will be "New Opport
for Planning Health Facilities."

Lederle Faculty Awards.—The Lederle Laboratories Di
American Cyanamid Company, announces that the foll
physicians are among the recipients of Lederle Medical F
awards for the year 1955:

Matthew N. Levy, department of physiology, Albany (N.Y.)
College.
David D. Thompson, department of physiology, Cornell Uni
Medical College, New York.
Wilbur H. Sawyer, department of physiology, New York Uni
College of Medicine, New York.
Albert M. Hand, department of pathology, University of Te
College of Medicine, Memphis, Tenn.

The Lederle Medical Faculty awards are for the purpo
strengthening the preclinical departments of medical scho
the U. S. and Canada by contributing to the support o
teaching and research activities of members of such de
ments who already have demonstrated high quality of per
ance but who have not yet attained permanent faculty ten

Mississippi Valley Medical Society.—The 20th annual me
of the Mississippi Valley Medical Society will be held a
Hotel Jefferson, St. Louis, Sept. 28-30. The program will in
panel discussions on hypertension, obstetrics, geriatrics, ps
somatic medicine, biliary tract diseases, and gastrointestinal
diseases. Dr. Elmer Hess, Erie, Pa., President, American
cal Association, will be the principal banquet speaker.

peakers at the banquet will be Dr. Victor B. Buhler, Kansas City, Mo., president, Missouri State Medical Association; Dr. Wendell L. Downing, Le Mars, Iowa, president-elect, Iowa State Medical Society; and Dr. F. Garm Norbury, Jacksonville, Ill., president, Illinois State Medical Society. During the scientific sessions Dr. Carroll J. Bellis, Long Beach, Calif., winner of the ssay contest, will present "The Management of Acute Bowel Obstructions"; Dr. Robert P. Cutler, U. S. Public Health Service Narcotics Hospital, Lexington, Ky., "Physician-Hospital Team n Treatment of the Narcotic Addict"; Dr. George A. Hellmuth, Milwaukee, "Treatment of Serious Cardiac Arrhythmias"; and Dr. William L. Watson, New York, "Head and Neck Cancer." Dr. Edward Henderson, Montclair, N. J., will serve as moderator for the panel on diseases of the aged and Dr. William C. Meninger, Topeka, Kan., as moderator for the panel on psychosomatic medicine. Thyroid problems will be considered by Dr. Arnold S. Jackson, Madison, Wis.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Railway Surgeons Meet in Las Vegas.—The Western Association of Railway Surgeons will hold its 52nd annual meeting Sept. 22-24 at the Hotel Thunderbird, Las Vegas, Nev. The sessions will open Thursday at 9:30 a. m. with the address of the president, Dr. Martin C. Lindem, Salt Lake City, followed by "Modern Concepts of Billroth I Gastric Resection with Analysis of Cases" by Dr. Earl Connolly, Omaha; "Evaluation of Pre-employment X-Ray of the Lower Back" by Dr. William L. Sucha, Omaha; and "Hyperventilation Syndrome" by Dr. John M. Read, Elko, Nev. A motion picture film, "Cardiac Arrest 'Resuscitation of Patients Who Die in the Operating Room,'" which will open the Friday program at 9 a. m., will be followed by:

Spontaneous Pneumothorax, Glenn Pierce, San Francisco.
Industrial Aspects of Epididymitis, William A. Summer, San Francisco.
Diagnosis and Treatment of Certain Anemias, Maurice E. Leonard, San Francisco.
Current Status of Antibiotic Therapy, John F. Waldo, Salt Lake City.

The Saturday program, which will include "Lower Extremity Injuries" by Dr. Robert W. Weber, Tucson, Ariz., "Nervous System Reactions Associated with Trauma" by Dr. Robert S. Wigston, Omaha, "Pulmonary Coccidioidomycosis" by Dr. James M. Fritz, Tucson, Ariz., and "The Problem of Sore Throat" by Dr. John F. Waldo, Salt Lake City, will conclude with "Professional Witness, Medicine or Witchery" by Edmund D. Leonard, *attorney-at-law, specialist in workmen's compensation* hearings before the Industrial Accident Commission, state of California, San Francisco.

LATIN AMERICA

Surgical Congress.—The second Panamerican Congress of the International College of Surgeons will be held simultaneously with the eighth Argentine meeting on thoracic surgery Oct. 22-26 in Mendoza, Argentina. The topics to be discussed include: Goiter: Medical and Surgical Treatment; Lung Abscess: Modern Treatments; Carcinoma of the Colon, Sigmoid, and Rectum: Surgical Treatment; Mycosis and Osteomyelitis of the Maxillary Bone; Patent Ductus: Surgical Treatment; and Peroral Endoscopy: Recent Advances. Information may be obtained from the Secretary, Caseros Av. 2153, Buenos Aires, Argentina, or from the Biblioteca Asociacion Medica Argentina Santa Fé 1171, Buenos Aires.

FOREIGN

Dermophlebologic Conference.—The sixth Colloquium of the French Society of Dermatology and Syphilography and the third International Conference on Phlebology will convene at Aix-en-Provence, France, Oct. 14-16, to consider "Trophic Disturbances of Venous Origin in the Legs" in the following aspects: surgical treatment in the lower limbs (except grafting); phlebological aspects (critical study of vascular lesions and trophic disorders); and dermatological studies. Correspondence should be addressed to the Clinique Dermatologique, Hotel-Dieu, Marseilles, France.

Congress on Legal and Social Medicine.—The 4th Congress of the International Academy of Legal and Social Medicine will be held in Genoa Oct. 13-17. The program will include consideration of the question "Can the application of an absolutely new therapy be considered as an experiment?" and of the following topics: "Acute and Chronic Poisoning by Arsenic in Legal Medicine," "The Medicolegal Valuation of Damage from Pneumoconiosis," "Depressive States as a Defense in Murder," and "Anthropology and Social Defense." Several postcongress tours have been planned to Rome, Florence, Venice, Naples, Milan, and the Italian lake region. Further information may be obtained from the general secretary's office of the congress (Istituto di Medicina Legale, via de Toni 12, Genoa, Italy).

Meetings on Dermatology and Syphilology.—The General Assembly of the International Union Against the Venereal Diseases and the Treponematoses will convene at the Barons' Hall, Maschio Angioino, Naples, Italy, Sept. 19-23. The general theme, "The Problem of Medicosocial Assistance to Marines in the Mediterranean Ports," will be introduced Monday at 3:30 p. m. Tuesday afternoon there will be an excursion to the new excavations at Baia and Cuma. Wednesday will be devoted to discussions of "Eventual Modifications to Be Added to the

Principles of the Antivenereal Fight Consequent to the Antibiological Therapeutics" and "Social Consequences of Nongonorrhoeal Urethritis." Demonstration of antivenereal documentaries will constitute the Friday morning program. Presentation of the patients at Professor Monacelli's Clinic will precede the afternoon lecture of Dr. E. H. Hermans, president of union.

The 40th National Congress of the Italian Society of Dermatology and Syphilology will be held at Dermosyphilopathic Clinic Hall, Policlinico, Naples, Sept. 22-25. Pemphigus will be discussed on Thursday. The Friday session will open at 9 a. m. with a symposium on cutaneous enzymology. The afternoon meeting, 4 p. m., will be devoted to presentation of clinical cases and to comments on dermatological iconography. Consideration will be given on Saturday to dermatological roentgenotherapy.

CORRECTION

Mitral Valvuloplasty.—In the filler by this title in The Journal, Aug. 20, 1955, page 1466, the word "less" should precede the word "good" in the seventh line.

MEETINGS

American Medical Association: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Oct. 12-14. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago, Director.

Academy of Psychosomatic Medicine, Hotel Plaza, New York, Oct. 6-8. Dr. Ethan Allan Brown, 75 Bay State Road, Boston 15, Secretary.

American Academy for Cerebral Palsy, Claridge Hotel, Memphis, Tenn., Oct. 10-12. Dr. Robert A. Knight, 869 Madison Ave., Memphis 3, Tenn., Secretary.

American Academy of Neurological Surgery, The Homestead, Hot Springs, Va., Oct. 27-29. Dr. Eben Alexander Jr., Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Palmer House, Chicago, Oct. 3-6. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Executive Secretary.

American Association of Medical Clinics, Curtis Hotel, Minneapolis, Nov. 4-6. Dr. Edwin P. Jordan, Box 58, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, LaSalle Hotel, Chicago, Oct. 3-7. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Director.

American Association of Nursing Homes, Hotel Muehlebach, Kansas City, Mo., Sept. 19-21. Mr. Ira O. Wallace, P.O. Box 366, New Castle, Ky., Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 27-29. Dr. James K. Stack, 700 N. Michigan Blvd., Chicago 11, Secretary.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Oct. 31-Nov. 2. Dr. M. N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Anesthesiologists, Hotel Statler, Boston, Nov. 4-5. Mr. John H. Hunt, 188 West Randolph St., Chicago 1, Executive Secretary.

American College of Cardiology Interim Meeting, Hotel Claridge, Memphis, Tenn., Nov. 10-12. Dr. Philip Reichert, Empire State Bldg., New York 1, Secretary.

American College of Gastroenterology, Hotel Shoreland, Chicago, Oct. 24-26. Dr. Joseph Shaiken, 33 West 60th St., New York 23, Secretary.

American College of Surgeons, Conrad-Hilton Hotel, Chicago, Oct. 31-Nov. 4. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American Dental Association, San Francisco, Oct. 17-20. Dr. Harold Hillenbrand, 222 East Superior St., Chicago 11, General Secretary.

American Fracture Association, Hotel Fontainebleau, Miami Beach, Fla., Sept. 19-22. Dr. Homer D. Junkin, Paris Hospital, Paris, Ill., Secretary.

American Heart Association, Yung Hotel, New Orleans, Oct. 22-26. Mr. Irving Hexter, 44 East 23d St., New York 10, Secretary.

American Hospital Association, Traymore Hotel, Atlantic City, N. J., Sept. 19-22. Dr. Edwin L. Crosby, 18 East Division St., Chicago 1 Director.

American Medical Writers' Association, Jefferson Hotel, St. Lou Sept. 30-Oct. 1. Dr. Harold Swanberg, P.O. Drawer 110, Quincy, Ill Secretary.

American Roentgen Ray Society, Palmer House, Chicago, Sept. 20-2 Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretar

American Society of Anesthesiologists, Hotel Statler, Boston, Oct. 2 Nov. 3. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph S Chicago 1, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicag Oct. 10-15. Dr. Clyde G. Culbertson, 1040-1232 West Michigan S Indianapolis, Secretary.

American Society of Plastic and Reconstructive Surgery, Atlan City, N. J., Sept. 25-30. Dr. Kenneth L. Pickrell, Duke Hospi Durham, N. C., Secretary.

American Society for the Study of Arteriosclerosis, Hotel Sherat Chicago, Nov. 6-7. Dr. O. J. Pollak, P.O. Box 228, Dover, D Secretary.

American Society of Tropical Medicine and Hygiene, Somerset Ho Boston, Nov. 2-5. Dr. John E. Larsh Jr., Dept. of Parasitolo School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, New Ocean Hou Swampscott, Mass., Oct. 24-26. Dr. Dean F. Smiley, 185 N. Wab Ave., Chicago 1, Secretary.

Association of American Physicians and Surgeons, Chicago, Oct. 7 Mr. Harry E. Northam, 185 N. Wabash Ave., Chicago 1, Execut Secretary.

Association of Life Insurance Medical Directors of America, Ho Statler, New York, Oct. 19-21. Dr. Henry B. Kirkland, P. O. Box 5 Newark, N. J., Secretary.

Association of Medical Illustrators, Hotel Barbizon Plaza, N York, Oct. 1-3. Miss Rose M. Reynolds, Univ. of Nebraska Coll of Medicine, Omaha 5, Neb., Corresponding Secretary.

Association of Military Surgeons of the U. S., Hotel Statler, Wa ington, D. C., Nov. 7-9. Colonel Robert E. Bitner, 1726 I St. N. Washington 6, D. C., Secretary.

Association of State and Territorial Health Officers, Hotel Wa ington, Washington, D. C., Nov. 6-12. Dr. Franklin D. Yoder, St Board of Health, Cheyenne, Wyo., Secretary.

Central Association of Obstetricians and Gynecologists, Desh Hilton Hotel, Columbus, Ohio, Oct. 5-8. Dr. Edwin J. DeCosta, Su 602, 116 S. Michigan Ave., Chicago 3, Secretary.

Central Neuropsychiatric Association, The Broadmoor, Color Springs, Colo., Oct. 20-22. Dr. Hamilton Ford, 112 North Bouleva Galveston, Tex., Secretary.

Central Society for Clinical Research, Drake Hotel, Chicago, N 4-5. Dr. Robert H. Ebert, 950 East 59th St., Chicago 37, Secret

Clinical Orthopaedic Society, Skirvin Hotel, Oklahoma City, Sept. Oct. 1. Dr. Marcus J. Stewart, 869 Madison Ave., Memphis, Te Executive Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 10 Dr. Arthur H. Dearing, 203 N. Wabash Ave., Chicago 1, Execu Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, S 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Ex tive Secretary.

Congress of Neurological Surgeons, *Hotel Statler, Los Angeles,* 27-29. Dr. Philip D. Gordy, 1007 Delaware Ave., Wilmington, D Secretary.

Delaware, Medical Society of, Delaware Academy of Medic Wilmington, Oct. 17-18. Dr. Norman L. Cannon, 621 Delaware A Wilmington, Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Wa ington, D. C., Oct. 10-12. Mr. Theodore Wiprud, 1718 M St., N. Washington 6, D. C., Executive Director.

Gerontological Society, Sheraton-Belvedere Hotel, Baltimore, Oct. 29. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 27-28. Dr. Bark Beidleman, 1750 N. Palafox St., Pensacola, Fla., Secretary.

Indiana State Medical Association, French Lick Springs Hotel, Fre Lick, Oct. 16-19. Mr. James A. Waggener, 23 East Ohio St., In anapolis 4, Executive Secretary.

Industrial Health Conference, Shamrock Hotel, Houston, Texas, Se 22-23. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Tex Chairman.

Inter-Society Cytology Council, Statler Hotel, Cleveland, Nov. 11- Dr. Paul F. Fletcher, 634 N. Grand Blvd., St. Louis 3, Secretary.

Kansas City Southwest Clinical Society, *Municipal Auditorium,* Kan City, Mo., Oct. 3-6. Dr. W. M. Kitchen, 306 E. Twelfth St., Kan City 6e, Mo., Secretary.

Kentucky State Medical Association, Louisville, Sept. 27-29. Mr. J. Sanford, 620 S. Third St., Louisville, Executive Secretary.

Michigan State Medical Society, Pantlind Hotel, Grand Rapids, Se 26-30. Dr. L. Fernald Foster, 606 Townsend St., Lansing 5, Secreta

Midwest Conference on Rheumatic Diseases, Henry Ford Hospi Detroit, Oct. 5. Dr. J. J. Lightbody, 7338 Woodward Ave., Detroit Medical Director.

Mississippi Valley Medical Society, Jefferson Hotel, St. Louis, Sept. 28-30. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Mississippi Valley Trudeau Society, Hotel Savery, Des Moines, Iowa, Oct. 14. Dr. Harold G. Curtis, Sunny Acres, Cuyahoga County Tuberculosis Hospital, Cleveland 22, Chairman, Program Committee.

National Association for Mental Health, Indianapolis, Nov. 4-6. Mr. Robert M. Heininger, 1790 Broadway, New York 19, Director.

New Hampshire Medical Society, Mt. Washington Hotel, Bretton Woods, Sept. 29-Oct. 1. Dr. Warren H. Butterfield, 18 School St., Concord, Secretary.

Oklahoma City Clinical Society Conference, Oklahoma City, Oct. 24-27. Dr. Charles E. Leonard, 512 Medical Arts Bldg., Oklahoma City 2, Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 24-27. Mrs. Anne K. Ramsey, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Oregon State Medical Society, Hotel Heathman, Portland, Sept. 28-Oct. 1. Dr. Richard R. Carter, 1020 S.W. Taylor St., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 18-23. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Postgraduate Assembly in Endocrinology and Metabolism, Indianapolis, Sept. 26-Oct. 1. Dr. John J. Mahoney, Assistant Dean, Indiana University School of Medicine, 1040 W. Michigan St., Indianapolis 7.

Regional Meetings, American College of Physicians:

Billings, Mont., Oct. 7-8. Dr. Harold W. Gregg, 103 North Wyoming St., Butte, Governor.

Charleston, S. C., Oct. 7-8. Dr. Robert Wilson, 165 Rutledge Ave., Charleston, S. C., Governor.

Buffalo, N. Y., Oct. 14. Dr. John H. Talbot, 100 High St., Buffalo 3, N. Y., Governor.

Madison, Wis., Oct. 15. Dr. Frederick W. Madison, 425 East Wisconsin Ave., Milwaukee 2, Governor.

Louisville, Ky., Nov. 5. Dr. Sam A. Overstreet, 332 West Broadway, Louisville, Ky., Governor.

Newark, N. J., Nov. 9. Dr. Edward C. Klein Jr., 6 S. Kingsman Rd., South Orange, N. J., Governor.

Society of Clinical Surgery, Hotel Roosevelt, New Orleans, Nov. 11-12. Dr. Frank F. Allbritten Jr., University of Kansas Medical Center, Kansas City, Mo., Secretary.

Tennessee Valley Medical Assembly, Read House, Chattanooga, Tenn., Oct. 3-4. Dr. Harry E. Jones, 109 Medical Arts Bldg., Chattanooga 2, Tenn., Secretary.

The Constantinian Society, Sheraton-Park Hotel, Washington, D. C., Oct. 26-29. Dr. C. F. Shook, P. O. Box 1035-36, Toledo 1, Ohio, Secretary.

Tri-State Medical Society, Grim Hotel, Texarkana, Tex., Sept. 28-29. Dr. Karlton H. Kemp, 408 Hazel St., Texarkana, Ark., Secretary.

Vermont State Medical Society, Mt. Washington Hotel, Bretton Woods, N. H., Sept. 29-Oct. 1. Dr. James P. Hammond, 337 South St., Bennington, Secretary.

Virginia, Medical Society of, Hotel Jefferson, Richmond, Oct. 16-19. Mr. Robert I. Howard, 105 West Franklin St., Richmond, Executive Secretary.

Western Association of Railway Surgeons, Las Vegas, Nev., Sept. 22-24. Dr. Leo L. Stanley, 1322 Fifth Ave., San Rafael, Calif., Secretary.

Western Orthopedic Association, The Reef, Honolulu, Hawaii, Nov. 7-10. Dr. Ivar J. Larsen, 1133 Punchbowl, Honolulu 13, Hawaii, Secretary.

Western Society of Electro-Encephalography, Westward Ho Hotel, Phoenix, Ariz., Nov. 10-12. Dr. Sylvester N. Berens, 902 Boren Ave., Seattle, Secretary.

FOREIGN AND INTERNATIONAL

Canadian Society for the Study of Fertility, Royal York Hotel, Toronto, Ont., Canada, Oct. 6-8. Dr. Earl R. Plunkett, 469 Waterloo St., London, Ont., Canada, Secretary.

Conference of International Union for Health Education of the Public, Rome, Italy, Apr. 27-May 5, 1956. Mr. Lucien Viborel, 92 rue St. Denis, Paris 1er, France, Secretary-General.

Congress of International Association of Limnology, Helsinki, Finland, July 26-Aug. 7, 1956. For information address: Dr. H. Luther, Snellmansgatan 16 C 36, Helsinki, Finland.

Congress of International Association of Logopedics and Phoniatrics, Barcelona, Spain, Sept. 3-7, 1956. Dr. J. Perello, Provenza 319, Barcelona 9, Spain, Secretary-General.

Congress of International Society of Hematology, Hotel Statler, Boston, Mass., U.S.A., Sept. 3-8, 1956. Dr. W. C. Moloney, 39 Bay State Road, Boston, Mass., U.S.A., Secretary.

Congress of International Society for Research on Anesthesia, Miami Beach, Fla., U.S.A., Mar. 12-15, 1956. For information write: Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland 12, Ohio, U. S. A.

Congress of International Union of Railway Medical Services, Dubrovnik, Yugoslavia, Sept. 19-24. Dr. Jovanovic, Head Office, Yugoslav Railway, Belgrade, Yugoslavia, President.

Congress of International Union Against Venereal Diseases, Naples, Italy, Sept. 25-28. For information address: Prof. Monacelli, University of Naples, Dept. of Dermatology, Naples, Italy.

Congress of Latin Society of Ophthalmology, Madrid, Spain, April 24-28, 1956. For information address: Dr. Costi, Montalban 3, Madrid, Spain.

European Congress of Allergology, Florence, Italy, May 1956. Prof. Umberto Serafini, Largo della Gancia 5, Rome, Italy, Secretary-General.

European Symposium on Vitamin B_{12}, Hamburg, Germany, May 1956. For information write: Doz. Dr. H. Bauer, Nervenklinik, Hamburg-Eppendorf, Germany.

International Academy of Legal and Social Medicine, Plenary Conference, Genoa, Italy, Oct. 13-17. Prof. Domenico Macaggi, Institut de Medicine legale, Universite de Genes, Genes, Italy, President.

International Academy of Pathology, Cincinnati, Ohio, U. S. A., April 24-25, 1956. Dr. F. K. Mostofi, Armed Forces Institute of Pathology, Washington 25, D. C., U. S. A., Secretary.

International Congress of Allergology, Rio de Janeiro, Brazil, S. A., Nov. 6-13. Dr. Bernard N. Halpern, 197 boulevard St. Germain, Paris 7^{e}, France, Secretary General.

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. Fenton, National Research Council, Division of Anthropology and Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress of European Society of Haematology, Freiburg i,Br., Germany, Sept. 20-24. Prof. Dr. L. Heilmeyer, Hugstetter Strasse 55, Freiburg i,Br., Germany, Chairman.

International Congress for the History of Science, Florence and Milan, Italy, Sept. 3-10, 1956. Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy, Secretary-General.

International Congress of Hydatid Disease, Athens, Greece, Sept. 14-18, 1956. Prof. B. Kourias, Croix-Rouge Hellenique, 1 rue Mackenzie King, Athens, Greece, Secretary-General.

International Congress of Internal Medicine, Madrid, Spain, Sept. 19-23, 1956. Dr. J. C. De Oya and Dr. J. Gimena, Hostaleza No. 90, Madrid, Spain, Secretaries.

International Congress of International College of Surgeons, Buenos Aires, Argentina, S. A., Nov. 19-24, 1956. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress of International Society of Bronchoesophagology, Buenos Aires, Argentina, S. A., Oct. 28-29. Dr. Juan Carlos Arauz, Cangallo 4015, Buenos Aires, Argentina, S. A., Secretary General.

International Congress of Medical Professional Jurisdiction, Medical Ethics, and Comparative Medical Law, Paris, France, Sept. 30-Oct. 3. Dr. J. R. DeBray, Conseil National de L'Ordre des Medécins, 60, Boulevard Latour-Maubourg, Paris 7e, France, Secretary General.

International Congress of Neo-Hippocratic Medicine, Montecatini, Terme, Italy, May 20-22, 1956. Prof. P. Delore, 13 rue Jarente, Lyon, France, Secretary-General.

International Congress of Paediatrics, Copenhagen, Denmark, July 22-27, 1956. Professor P. Plum, Rigshospitalet, Copenhagen, Denmark, President.

International Congress of Physical Medicine, Copenhagen, Denmark, August 20-24, 1956. Dr. B. Strandberg, Kobenhavns amts sygehus i Gentofte, Dept. of Rheumatology and Physical Medicine, Hellerup, Denmark, Honorable Secretary.

International Congress of Radiology, Mexico, D. F., Mexico, July 22-28, 1956. Dr. Jose Noriega, Tepic 126 (2e piso), Mexico, D. F. 7, Mexico, Secretary General.

International Congress of World Confederation for Physical Therapy, New York, New York, U. S. A., June 17-23, 1956. For information address: Miss Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York, U. S. A.

International General Medical Congress, University of Rosario Medical College, Rosario, Argentina, S. A., Nov. 7-12. Dean Jose Imhoff, Santa Fé 3100, Rosario, Argentina, S. A., Chairman.

International Physiological Congress, Brussels, Belgium, July 29-Aug. 5, 1956. For information address: Prof. J. Reuse, Faculte de Medicine et de Pharmacie, 115 Boulevard de Waterloo, Brussels, Belgium.

International Professional Union of Gynecologists and Obstetricians, Madrid, Spain, Sept. 28-29, 1956. Dr. Jacques Courtois, 1 rue Racine, St-Germain-en-Laye (S and O), France, Permanent International Secretary-General.

Medical Journalism Meeting, Vienna, Austria, Sept. 23. For information address: World Medical Association, 345 East 46th St., New York, N. Y., U.S.A.

North Queensland Medical Conference, Cairns, North Queensland, Australia, June 25-30, 1956. Dr. W. R. Horsfall, P.O Box 672, Cairns, N.Q., Australia, Secretary.

Pan American Congress of International College of Surgeons, Mendoza City, Argentina, S. A., Oct. 22-26. For information address: Secretary, Caseros Av. 2154, Buenos Aires, Argentina, S. A.

Pan American Congress of Ophthalmology, Santiago, Chile, S. A., Jan. 9-14, 1956. Dr. Rene Contardo, Huerfanos 930, Of. 74, Santiago, Chile, Secretary General.

Pan American Medical Social Convention, Bogota, Colombia, S. A., Oct. 15-22. Dr. Leopoldo E. Araujo, Avenida de los Presidentes Num. 506, Apartado 2589, La Habana, Cuba, Secretary.

Pan American Medical Women's Alliance, Santiago, Chile, March 6-13, 1956. For information address: Dr. Eva Cutright, 458 Beall Ave., Wooster, Ohio, U. S. A.

Venezuelan Congress of Medical Sciences, Caracas, Venezuela, S. A., Nov. 18-26. Dr. A. L. Briceno Rossi, Apartado 4412, Ofic. del Este, Caracas, Venezuela, S. A., Secretary General.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

World Medical Association, Vienna, Austria, Sept. 20-26. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary General.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* New York City, Oct. 23-27. *Written.* Various locations in United States and Canada, July 20, 1956. Final date for filing application is Jan. 20. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: *Oral.* Washington, D. C., Oct. 14-16. Final date for filing application was March 15. Sec., Dr. B. M. Kesten, One Haven Ave., New York 32, N. Y.

American Board of Internal Medicine: *Oral.* Portland, Ore., Sept. 14-16; Chicago. Nov. 30-Dec. 1. *Subspecialties. Cardiovascular Disease.* Chicago, Nov. 30. The closing date for acceptance of applications for gastroenterology was Feb. 1, and for cardiovascular disease the closing date was June 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* New Haven, November. Oral examinations given in Spring and Fall. Final date for filing application for the Spring examination is October 1, for the Fall examination April 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Written Examination and submission of Case Reports. Part I.* Various locations in United States and Canada, and military centers outside of the Continental United States. Feb. 3, 1956. Final date for filing application is Oct. 1. *Oral and Pathological Examinations. Part II.* Chicago, May 11-20, 1956. Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Practical Examination.* Chicago, Oct. 3-7. Written. January 24-26, 1956. *Practical Examination.* San Francisco, June 18-21, St. Louis. Oct. 20-25. Applications for 1957 written examination must be filed before July 1, 1956. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral.* Jan. 26-27. Final date for filing application was Aug. 15. *Written.* Various cities, April 1956. Final date for filing application is Nov. 30. Sec., Dr. Harold A. Sofield, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 3-7. Final date for filing application is April. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: *Written and Practical.* Chicago, Oct. 6-8. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago.

American Board of Pediatrics: *Oral.* Chicago, Oct. 7-9; and Washington, D. C., Dec. 2-4. Admin. Sec., Mrs. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation. *Parts I and II.* Chicago, June 16-17. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Philadelphia, Sept. 22-24. Corres. Sec., Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *Certification in Public Health.* Kansas City, Mo., Nov. 10-12. Sec.-Treas., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore 5.

American Board of Proctology: *Part II.* Philadelphia, Sept. 17. Sec., Dr. Stuart T. Ross, 131 Fulton Ave., Hempstead, N. Y.

American Board of Psychiatry and Neurology: San Francisco, Oct. 17-18; New York City, December, Philadelphia, April 16-18, 1956. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: Chicago, Dec. 4. Final date for filing applications for the fall examination was July 1. Candidates who will complete their training by Dec. 31 will be eligible to appear for this examination. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Centers throughout the United States, in Europe and in the Far East, Oct. 26 and March 28. Closing date for the October examination was July 1 and for the March examination is December 1. *Part II.* Buffalo, Sept. 26-27; Chicago, Oct. 27-28; New York City, Nov. 14-15; St. Louis, Dec. 12-13; New Orleans, Jan. 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, Mar. 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

The Board of Thoracic Surgery: *Written.* Various Centers, Sept. 9. Final date for filing applications was July 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Ave., Detroit 2.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circul tion magazines and forthcoming network television programs o medical subjects is published each week only for the inform tion of readers of The Journal. *Unless specifically stated, th American Medical Association neither approves nor disappro of the articles and programs reported.*

TELEVISION

Monday, Sept. 19

ABC-TV, 9:30 p. m. EDT. "Medical Horizons" will origina from the University of New York College of Medicine, whi is featuring a report on its department of psychiatry's perce tion and personality study. Presented in cooperation with t American Medical Association.

Tuesday, Sept. 20

NBC-TV, 9:30 p. m. EDT. "March of Medicine" inaugura its fall series with an up-to-the-minute report on the at in medicine, particularly in the use of radioactive isoto to combat cancer. Features pickups from the University Texas M. D. Anderson Hospital, in Houston, Columbia U versity College of Physicians and Surgeons, in New York, a Johns Hopkins University, in Baltimore. Presented in operation with the American Medical Association.

Wednesday, Sept. 21

NBC-TV, 11:30 a. m. EDT. "Medical and Health News w Howard Whitman," a segment of the "Home" program.

MAGAZINES

Saturday Evening Post, Sept. 10, 1955

"Where Are We Now on Polio?" by Steven M. Spencer

In a roundup of events since the Salk poliomyelitis vacc was announced last April, Mr. Spencer states: "In spite all difficulties, most scientists familiar with the situat believe that the vaccine, developed by Dr. Jonas E. Sa . . . has great promise. And there is every reason to h that the Salk formula, or a modification of it, will in ti reduce the toll of paralytic polio." The author's conclus is that, "Until many more facts are in, the question whether or not to give the Salk vaccine remains one the doctor and the parent to decide."

Town Journal, September, 1955

"Triumph over Mental Illness," by Howard LaFay

"Science has at last found chemicals—drugs with stra names like chlorpromazine, reserpine and Frenquel—t help to heal sick minds." The author reports that research can muster strong evidence to support their ideas ab the physical nature of mental disease and that drugs, wh combined with psychotherapy, often "lead the way permanent, basic cures."

Family Weekly Magazine, Sept. 11, 1955

"Do You Make Par as a Patient?" by Charles and Je Komaiko

A series of questions reveal the importance of a pro patient-doctor attitude.

Life, Sept. 5, 1955

"Poison Ivy Picker of Pennypack Park"

"Farmers and suburbanites [have] reason to hope for t first practical ivy immunizer before the poisoning seas of 1956." Tests are being conducted on the efficacy of experimental poison ivy vaccine developed by Columb *University's Dr. Charles R. Dawson.*

GOVERNMENT SERVICES

AIR FORCE

Industrial Physician Wanted.—A vacancy exists at Brookley Air Force Base, Alabama, for a medical officer in industrial health and medicine, GS-12, $7,570 per annum. Persons interested in this position should submit an application for federal employment (standard form 57) to W. N. Ballard, Chief, Placement and Employee Relations Branch, Civilian Personnel Division. These federal forms are available at any first-class or second-class post office.

ARMY

Personal.—Col. Clinton S. Maupin, M. C., a nuclear energy authority, has been made a special assistant to the surgeon general.——Col. Charles L. Leedham, M. C., chief, education and training division, Office of the Surgeon General, retired from the Army on Aug. 31 after 26 years of service. He has accepted a position as director of education, Frank E. Bunts Educational Institute of the Cleveland Clinic Foundation, Cleveland.——The commandant of the Army Medical Service Graduate School, John R. Wood, at Walter Reed, has been made a brigadier general. Prior to coming to Walter Reed, General Wood was chairman of the Medical Research and Development Board in the surgeon general's office.

ATOMIC ENERGY COMMISSION

Dr. Shilling Named to AEC Post.—The Atomic Energy Commission announced the appointment of Dr. Charles W. Shilling as special assistant to the director of the commission's division of biology and medicine. Dr. Shilling, who recently retired from the Navy after 28 years of service, will assist Dr. John C. Bugher, director of the division of biology and medicine, in the administration and coordination of the commission's medical, biological, and biophysics research programs. Dr. Shilling, born in Indiana, holds a B.S. degree from Taylor University in Indiana and a B.A. degree from the University of Michigan. He received an M.D. degree from the University of Michigan Medical School and attended the Harvard School of Public Health in 1932-1933.

In the Navy, Dr. Shilling was assigned to various submarine bases. He conducted research in safety, salvage, and escape equipment for submarines. He became a qualified deep sea diver. In 1939, he was senior medical officer in the rescue of personnel from the stricken submarine U.S.S. Squalus. In 1947, Dr. Shilling joined the Office of Naval Research, where he served for six years. In 1953 he was transferred to the Naval Academy, where he filled concurrent assignments as senior medical officer and head of the department of hygiene.

Discontinue Distribution of Cyclotron-Produced Radioisotopes.—The chairman of the U. S. Atomic Energy Commission has announced that the commission will discontinue, effective Nov. 30, its program for the processing and distribution of cyclotron-produced radioisotopes. The decision will not affect the commission's program for the production and distribution of reactor-produced radioisotopes and electromagnetically-concentrated stable isotopes. The bulk of the radioisotopes distributed by the commission has been produced in reactors. The commission will also continue to perform, on payment of applicable charges, service irradiations in its cyclotrons. The AEC began the production and distribution of cyclotron-produced radioisotopes in 1949 to assist medical and biological research by providing radioisotopes that could not be produced in a nuclear reactor or could not be prepared from reactor-produced radioisotopes to meet activity specifications. The more important of these radioisotopes are beryllium 7, sodium 22, arsenic 73 and 74, iron 59, zinc 65, and iodine 125. This program is being discontinued because it is an activity that, it appears, may now be performed by private groups, and the commission program is no longer necessary to make these materials available for research. A total of 793 shipments of cyclotron produced radioisotopes with a total activity of 4,065 mc. was distributed from June, 1949, through June, 1955.

NAVY

Annual Medico-Dental Symposium.—The sixth Annual Military Medico-Dental Symposium for all armed forces medical personnel of the United States will be held at the U. S. Naval Hospital, Philadelphia, Oct. 17-23. The program has been planned to present professional advances developed by both civilian and military services. Special sessions are planned for officers in the medical, surgical, dental, and administrative fields. Medical department officers, whether on active or inactive duty, are urged to attend. Medical department officers on active duty may be given "authorization orders" (at no expense to the government) in accordance with current instructions. The chief of naval personnel approved this symposium for the awarding of retirement point credits to those eligible Naval Reserve officers attending. Information on the symposium may be obtained from the District Medical Office, Building 4, U. S. Naval Base, Philadelphia 12, Pa.

Medical Reserve Program Officer Billets.—Applications for full-time active duty as a medical reserve program officer are desired from qualified reserve medical officers whose rank is commander or captain and who desire to serve on active duty for a period of two years or longer. The duties of a medical reserve program officer, whose function is to assist the district medical officer in carrying out the directives of the commandant in regard to the medical reserve program, offer an interesting job to the senior reserve medical officer. In addition to accruing one retirement point toward Naval Reserve retirement for each day of active duty performed, medical reserve program officers receive the full pay and allowances of their grade plus the additional $100 per month authorized for medical officers on extended active duty. For information, write to the Chief, Bureau of Medicine and Surgery (Code 36), Navy Department, Washington 25, D. C.

Research Unit No. 3; Cairo, Egypt.—Dr. Dorothy M. Horstmann, associate professor of preventive medicine, Yale University School of Medicine, New Haven, Conn., presented an informal lecture on poliomyelitis on July 27. Dr. Max Theiler, director, Rockefeller Foundation Laboratories in the Rockefeller Institute, visited the unit on Aug. 3. Dr. Theiler, who was awarded a Nobel prize for work on a yellow fever vaccine, was making a tour of Africa in connection with his work on virus diseases. Capt. Joe L. Stockard, M. C., U. S. Army, visited the unit the first week of August, while returning to the United States after spending 10 months at the U. S. Army medical research unit at the Medical Research Institute, Kuala Lumpur, Malaya. Capt. Stockard spoke to the staff on his experiences with leptospirosis in Malaya, a disease that has been responsible for one-third of cases of persons hospitalized for fever of undetermined etiology in Malaya.

VETERANS ADMINISTRATION

Personal.—Dr. Oliver W. Greer, manager of the Veterans Administration Hospital in Newington, Conn., has been appointed manager of the VA Hospital at Lake City, Fla., succeeding Dr. Oma E. Herndon, who was transferred to VA regional office in Atlanta, Ga.——Dr. William K. Freeman, manager, VA Hospital in Gulfport, Miss., has been named to the same position at the hospital in Downey, Ill., succeeding Dr. Lee G. Sewall, who has been appointed manager of the VA Hospital in Pittsburgh.

DEATHS

Branton, Alloys Franklin ⊕ Chattanooga, Tenn.; born in Minneapolis May 19, 1895; University of Minnesota Medical School, Minneapolis, 1920; served during World War I; fellow of the American College of Hospital Administrators; past-president and secretary of the Minnesota Hospital Association and the Tennessee Hospital Association; member of the council on government relations and committee of veterans' relations of the American Hospital Association; president-elect of the Chattanooga Area Heart Association; in May, 1954, was appointed a member of the state commission on hospital licensing; retired as administrator of the Carver Memorial Hospital, T. C. Thompson Children's Hospital, and the Baroness Erlanger Hospital, where he died July 26, aged 60, of cerebral hemorrhage.

Palmer, Theodore Sherman, Washington, D. C.; born in Oakland, Calif., Jan. 26, 1868; Georgetown University School of Medicine, Washington, 1895; in 1889 joined the Bureau of the Biological Survey of the U. S. Department of Agriculture, retiring July 1, 1933; secretary of the American Ornithologists Union from 1917 to 1937; president emeritus since 1941 of the District of Columbia Audubon Society; vice-president of the National Association of Audubon Societies from 1905 to 1935 and of the American Society of Mammalogists from 1928 to 1934; member of many scientific societies; author of several books; died July 23, aged 87, of chronic myocarditis and cardiovascular renal disease.

Darby, John Charles, Hudson, Ohio; born in 1874; Western Reserve University Medical Department, Cleveland, 1900; from 1901 to 1911 on the faculty of his alma mater; for many years secretary of the Soldiers and Sailors Monument Commission; veteran of the Spanish-American War; served as major on the Mexican border; the French government awarded him the Croix de Guerre for his World War I service; served on the staffs of the University Hospitals and Woman's Hospital in Cleveland; died in the Lakeside Hospital, Cleveland, July 30, aged 80, of coronary disease.

Shepherd, Ford ⊕ Santa Cruz, Calif.; Stanford University School of Medicine in San Francisco, 1940; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; interned at the San Francisco Hospital, where he later served a residency; formerly a resident at the Sonoma County Hospital in Santa Rosa and the Stanford University Hospitals in San Francisco; served during World War II; died July 17, aged 42, of subacute yellow atrophy of the liver and myocardial insufficiency.

Abrams, Julius Leonard, New York City; University and Bellevue Hospital Medical College, New York City, 1917; member of the Medical Society of the State of New York; died April 1, aged 66, of a heart attack.

Allen, Joseph Lee ⊕ Greenfield, Ind.; Medical College of Indiana, Indianapolis, 1904; served as coroner of Hancock County; died in the Veterans Administration Hospital, Marion, June 4, aged 80, of coronary thrombosis.

Askew, Rufus Andrew ⊕ Atlanta, Ga.; University of Georgia School of Medicine, Augusta, 1938; member of the Industrial Medical Association; served during World War II; died July 5, aged 48.

Beard, Joseph Sidney ⊕ Edison, Ga.; Atlanta College of Physicians and Surgeons, 1910; died June 1, aged 75, of cancer.

Brower, Charles J. ⊕ Spring City, Pa.; Jefferson Medical College of Philadelphia, 1894; an associate member of the American Medical Association; served on the staff of the Phoenixville (Pa.) Hospital; died April 25, aged 83, of cancer of the bladder.

Burrell, Henry J. ⊕ Benton Harbor, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1914; served during World War I; formerly on the staff of the Mercy Hospital; died in Dowagiac July 25, aged 81.

Butler, Edmund William ⊕ San Francisco; Cooper Medical College, San Francisco, 1911; formerly on the faculty of Stanford University School of Medicine; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; served overseas during World War I; past-president of the San Francisco Surgical Society; associated with the Chinese, San Francisco, St. Mary's, and Stanford University hospitals; died in Sebastopol, July 31, aged 68.

Carey, David Stewart ⊕ Freehold, N. J.; Fordham University School of Medicine, New York City, 1909; served during World War I; for many years school physician and county jail physician; on the staff of the Monmouth Memorial Hospital in Long Branch, where he died July 19, aged 69, of adenocarcinoma of the stomach with metastases.

Carter, Edward Perkins, Bronxville, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; member of the Association of American Physicians; formerly on the faculty of Western Reserve University School of Medicine in Cleveland, where he was on the staff of the Lakeside Hospital, and the Johns Hopkins University School of Medicine in Baltimore; died July 31, aged 85, of pernicious anemia.

Corry, John A. ⊕ Barnesville, Ga.; University of Georgia Medical Department, Augusta, 1898; served as chairman of the county board of health and as a member of the state board of health; charter member and first president of Barnesville Rotary Club; died July 4, aged 78.

Cowden, Arthur McCluney ⊕ Mobile, Ala.; University of Alabama School of Medicine, 1916; member of the American Academy of General Practice; past-president of the Medical Society of Mobile County; served during World War I; medical examiner for the Mobile County Draft Board during World War II; past-president of the staff of the Mobile Infirmary; on the staffs of the Mobile City Hospital and the Providence Hospital; died Aug. 1, aged 65, of coronary occlusion.

Daniele, Joseph Americo, Crestline, Calif.; University of California Medical School, San Francisco, 1936; interned at St. Joseph's Hospital in San Francisco; died July 27, aged 45, of pulmonary tuberculosis.

Dean, Frank Wilson ⊕ Council Bluffs, Iowa; University of Minnesota College of Medicine and Surgery, Minneapolis, 1890; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staff of the Jennie Edmundson Memorial Hospital; died July 3, aged 92, of arteriosclerotic heart disease.

deBoe, Michael Price ⊕ Coral Gables, Fla.; born in Bedford County, Va., Nov. 29, 1885; University College of Medicine, Richmond, 1908; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; associated with the Jackson Memorial, Victoria, and Mercy hospitals in Miami; died in the Veterans Administration Hospital June 28, aged 69, of myocardial infarction and coronary arteriosclerosis.

Deuterman, Joel LeRoy ⊕ Elgin, Ill.; University of Virginia Department of Medicine, Charlottesville, 1930; interned at the Virginia Mason Hospital in Seattle; later a fellow at the Mayo Foundation in Rochester, Minn.; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; served during World War II; on the staffs of the Sherman Hospital and St. Joseph Hospital, where he died Aug. 7, aged 53, of malignant tumor of the pituitary gland.

⊕ Indicates Member of the American Medical Association.

Dew, Roderick ⊕ Woodford, Va.; Medical College of Virginia, Richmond, 1892; died July 1, aged 88, of coronary thrombosis.

Dunn, Charles Hunter, Hopewell Junction, N. Y.; Harvard Medical School, Boston, 1900; at one time on the faculty of his alma mater; died in St. Francis Hospital in Poughkeepsie July 19, aged 79, of injuries received in an autombile accident.

Edmunds, Fred Andrew ⊕ Bethel, Vt.; Baltimore Medical College, 1903; died July 17, aged 77, of coronary infarction.

Edwards, Robert William ⊕ La Grange, Ill.; University of Illinois College of Medicine, Chicago, 1926; member of the American Academy of General Practice; served during World Wars I and II; since May, 1950, health officer of La Grange; on the staffs of the West Suburban Hospital in Oak Park, MacNeal Memorial Hospital in Berwyn, and the Hinsdale (Ill.) Sanitarium and Hospital; died Aug. 10, aged 56, of coronary occlusion.

Emery, Walter Vanalystyne ⊕ Chester, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1906; past-president of the Delaware County Medical Society; on the staffs of the J. Lewis Crozer Homeopathic Hospital and the Chester Hospital in Chester, and the Taylor Hospital in Ridley Park, where he died July 20, aged 74, of cerebral vascular accident.

Gould, William B. ⊕ Glenwood, Ark. (licensed in Arkansas in 1903); served as president of the Bank of Glenwood and as a member of the board of education; died Aug. 2, aged 81, of arteriosclerotic heart disease.

Griffiths, Albert Farnsworth, Bayside, N. Y.; Harvard Medical School, Boston, 1901; died July 22, aged 77, of coronary occlusion.

Grindle, J. Lowell, Northeast Harbor, Maine; Medical School of Maine, Portland, 1903; died July 8, aged 78.

Hall, Chester Garfield ⊕ Portland, Ore.; University of Oregon Medical School, Portland, 1904; associated with St. Vincent's, Emanuel, and Providence hospitals; died in Gold Beach July 23, aged 74, of a heart attack.

Hammer, Howard John ⊕ San Francisco; Wayne University College of Medicine, Detroit, 1935; specialist certified by the American Board of Urology; member of the American Urological Association; served during World War II; on the staffs of the Stanford University, St. Francis Memorial, and French hospitals; died Aug. 3, aged 46.

Hanson, Clarence B., Sioux City, Iowa; Sioux City College of Medicine, 1907; died July 21, aged 81.

Harms, Albert Oscar, Kansas City, Kan.; Kansas City (Mo.) Homeopathic Medical College, 1902; served on the staffs of the Bethany and St. Margaret's hospitals; died Aug. 3, aged 76, of coronary sclerosis.

Harris, Gracchus Crawford Jr., Navasota, Texas; Baylor University College of Medicine, Dallas, 1936; interned at the Jefferson Davis Hospital in Houston; served during World War II; died July 21, aged 46.

Keefe, George Gregory ⊕ West Hartford, Conn.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1922; on the staff of St. Francis Hospital, Hartford, where he died July 21, aged 59, of cerebral vascular accident.

Kibler, Francis Elmo ⊕ Colorado Springs, Colo.; University of Colorado School of Medicine, Denver, 1933; specialist certified by the American Board of Surgery; interned at the Ancker Hospital in St. Paul where he served a residency; served in the U. S. Naval Reserve during World War II; on the staffs of Glockner-Penrose Hospital, St. Francis Hospital, and Memorial Hospital; died May 11, aged 47, of cerebral vascular accident and hypertension.

Kirgan, Joseph William, Cincinnati; Miami Medical College, Cincinnati, 1903; died in Boardman River, Mich., July 5, aged 80.

Koefoot, Theodore Henry ⊕ Broken Bow, Neb.; Chicago College of Medicine and Surgery, 1913; served during World War I; died in Clarkson Hospital, Omaha, June 19, aged 64, of coronary arteriosclerosis.

La Fond, Dolor Joseph Arthur, Ponte Vedra Beach, Fla.; University of Tennessee College of Medicine, Memphis, 1919; member of the Massachusetts Medical Society; died July 2, aged 64.

Lang, William Peter ⊕ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1901; fellow of the American College of Surgeons; died in Wildwood, N. J., July 24, aged 76, of diabetes, cerebral hemorrhage, and arteriosclerosis.

Laws, Harry John ⊕ Lafayette, Ind.; University and Bellevue Hospital Medical College, New York City, 1907; early in his career secretary of the Tippecanoe County Medical Society; member of the American Academy of General Practice; city health officer; served during World War I; died May 20, aged 71, of coronary occlusion.

Leuty, Joseph David ⊕ Farmington, Wash.; Vanderbilt University School of Medicine, Nashville, Tenn., 1898; died in Medical Lake, June 18, aged 80, of a heart attack.

MacDougall, Walter Hope ⊕ Oswego, Ore.; University of Bombay, India, 1919; served during World War II; on the staff of the Good Samaritan Hospital in Portland, where he died June 29, aged 60, of coronary heart disease and cerebral thrombosis.

Mandelbaum, George Murray, Philadelphia; George Washington University School of Medicine, Washington, D. C., 1926; on the staff of the Albert Einstein Medical Center-Northern Division; died July 5, aged 53, of coronary disease.

Neuwelt, Frank ⊕ Gary, Ind.; University of Chicago Medical School, 1937; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; formerly a resident at the Michael Reese and the Cook County hospitals in Chicago; assistant professor of medicine at the Chicago Medical School; died in Wesley Memorial Hospital, Chicago; July 4, aged 43, of cerebral hemorrhage.

Parker, James William, Peoria, Ill.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1888; died in the Proctor Hospital April 4, aged 87, of cerebral hemorrhage and arteriosclerosis.

Petty, Lester Edwin, Borger, Texas (licensed in Texas under the Act of 1907); member of the State Medical Association of Texas; past-president of the Hutchinson-Carson Counties Medical Society; for many years city health officer; died May 30, aged 81, of emphysema and arteriosclerosis.

Rosser, Robert Guthrie ⊕ Vass, N. C.; North Carolina Medical College, Charlotte, 1909; member of the American Academy of General Practice; for many years secretary of the Moore County Medical Society; on the courtesy staff of the Moore County Hospital in Pinehurst; died in Pinehurst July 17, aged 74, of arteriosclerosis and uremia.

Scheffel, Carl, Miami, Fla.; College of Physicians and Surgeons, Boston, 1914; joint author of "Jurisprudence for Nurses" and author of "Medical Jurisprudence"; died July 18, aged 68, of coronary occlusion and diabetes mellitus.

Shurtz, Richard Charles ⊕ Champaign, Ill.; University of Illinois College of Medicine, Chicago, 1927; at one time coroner of Champaign County; died in the Mercy Hospital, Urbana, July 29, aged 60, of acute bacterial endocarditis.

Talbot, Robert Emmett ⊕ Wilder, Idaho; University of Colorado School of Medicine, Denver, 1914; served during World War II; on the staff of the Caldwell (Idaho) Memorial Hospital; died in Boise June 19, aged 65, of obstructive emphysema and bronchopneumonia.

Wilson, Benjamin Ralph ⊕ Sharpsburg, Ky.; University of Louisville (Ky.) School of Medicine, 1931; member of the American Academy of General Practice; member of the city council; on the staff of the Mary Chiles Hospital in Mount Sterling, where he died May 11, aged 52, of polycythemia vera with myeloid degeneration.

Yates, Joseph Earnest ⊕ Sacramento, Calif.; College of Physicians and Surgeons of San Francisco, 1904; for many years on the staffs of the Sutter General Hospital and Mercy Hospital; died July 19, aged 74, of cerebral hemorrhage and arteriosclerosis.

BRAZIL

Pulmonary Resection in Tuberculosis.—Dr. Jesus Zerbini and his co-workers in *Revista Paulista de Medicina* (46:325, 1955) reported on the results in 255 tuberculous patients in whom pulmonary resection was performed. Age of patients varied between 13 and 61 years, most being in the third decade of life. The authors performed 89 pneumonectomies, 113 lobectomies, 14 lobectomies plus segmental resections, and 39 simple segmental resections. Surgery was obligatory in 185 patients with extensive unilateral tuberculosis, tuberculomas, bronchiectasis, large cavities of the superior lobe, failure of collapsotherapy, and the like and elective only in those with localized lesions. The series was divided into the following three groups: the first included patients operated on without the use of antibiotics; the second, patients previously treated with streptomycin (mainly collapsotherapy failures); and the third, patients who before and after operation had had adequate treatment with antibiotics. The analysis of data shows a marked decrease of incidence and case fatality rates of all main postoperative complications. For instance, disseminations were found in 40.7% of the patients in the first group, in 18.4% of those in the second, and in 6.5% of those in the third, with a case fatality rate of 29.6% in the first group, 10.5% in the second, and no deaths in the third. Similarly, bronchial fistulas appeared in 48.1% of the patients in the first group, 21.0% of those in the second, and 15.1% of those in the third, while the case fatality rate was 28.8% in the first group, 10.5% in the second, and 1.3% in the third. As the authors' experience increased they observed a gradual decrease in large resections, while less mutilating operations became more frequent. Pneumonectomies, lobectomies, and simple segmental resections represented 40.7, 48.1, and 11.2% of the operations, respectively, in the first group, and 56.5, 42.1, and 1.4% in the second group. In the third group, pneumonectomies represented only 23.0%, lobectomies 44.7%, segmental resections 25.0%, and lobectomies plus segmental resections, 7.3%. The case fatality rate for pneumonectomies, 18.5 and 23.3% in the first and second groups, fell to 3.2% in the third. The case fatality rate for lobectomies fell from 25.9% in the first group to 10.5% in the second and 1.3% in the third. There was a similar reduction in the case fatality rate for segmental resections. The results observed in the active series were: clinically cured patients 74.5%; case fatality rate directly related to resection 11.7%; and case fatality rate indirectly related to resection 3.5%. Eighteen patients were operated on recently, with results still to be judged (6.2%). The separate study of each type of resection in the third and last group of 152 patients shows the results obtained in each operation: 35 pneumonectomies were performed showing 71.4% clinical cures and a case fatality rate of 14.2%; 68 lobectomies showed 91.9% clinical cures and a case fatality rate of 1.4%; 38 segmental resections showed 78.9% clinical cures and no deaths; and 11 lobectomies plus segmental resection showed 54.5% clinical cures and no deaths.

Infantile Diarrhea.—At a recent meeting of the Associação Paulista de Medicina, Dr. Guilherme Mattar and his co-workers of the department of pediatrics of the São Paulo State University presented a study on the disturbances of electrolytes in infantile diarrhea. They began by stating that the routine treatment of dehydration by means of a standardized plan, without the individualization of the losses of water and electrolytes in a particular patient, is not the best treatment for dehydrated children. The knowledge of the electrolytic alterations of the serum, through the determination of the several ions, contributes to a more correct therapeutic orientation, but it does not reveal the true deficits of the several electrolytes, owing to the disproportion between their losses and that of water. Only by means of precise metabolic balances may we determine in vivo the total quantitative losses of water and electrolytes in dehydration. The difficulties inherent in metabolic balance studies in small children explain the rarity of such investigations.

The authors performed their investigations on two children aged 4 and 9 months respectively. Both showed qualitatively similar disturbances with marked losses of sodium, chlorine, potassium, calcium, nitrogen, and, in one case, of phosphorus, independent of tissue destruction. The losses of sodium were predominant in the extracellular spaces, but the deviations of sodium toward the interior or the exterior of the cells, according to the phase of dehydration or recuperation, were significant. Comparable transfers of cellular potassium occur in the reverse direction to balance the deviation of sodium. Sodium lost from the extracellular fluid was equivalent to half (case 1) and twice (case 2) the estimated normal extracellular content of the infant. In both patients significant amounts of sodium lost from the extracellular spaces were due to transfer of this ion to the intracellular fluid. These transfers contributed to the establishment of acidosis, and they were equivalent to one and one-half times and two times the estimated normal content of the intracellular fluid or to about one-third of the total extracellular sodium. The losses of intracellular potassium were marked in both patients and could not be explained by the protein disintegration. These losses were estimated as 20 and 28.6%, respectively, of the estimated amount of intracellular potassium, or the equivalent of a little more than half the estimated extracellular sodium. Significant losses of calcium occurred in both infants. In one, loss of phosphorus not proportionate to loss of nitrogen was seen and equalled 20% of the estimated normal content of the tissues. Hypocalcemia appeared in the infant in case 1 when the acidosis was already corrected; loss of phosphorus was present in the second infant before the correction of acidosis. In both patients the symptoms and the biochemical disturbances frequently described in medical literature were not observed. The authors attributed this absence to the use by them early in the treatment of hydrating solutions with the ions necessary to replace the intracellular deficits.

Reservoirs of Schistosoma Mansoni.—At a recent meeting of the Brazillian Society of Hygiene, Dr. A. V. Martins, of the Minas Gerais State University, reported a new and unexpected aspect of the epidemiology of intestinal schistosomiasis. Impressed by the discovery by Kuntz and Schwetz in Africa of sylvatic reservoirs of Schistosoma mansoni, Dr. Martins, with the cooperation of the malaria division of the National Departpartment of Health, captured 210 animals, mostly rodents, in the state of Minas Gerais. Careful examination of these animals showed that 48 of them were naturally infected by S. mansoni, or a general infection index of 22.9%. The most important reservoir hosts found were rodents, such as Nectomys squamipes aquaticus (57.5% infected) and Rattus norvegicus (46.8% infected); however, a marsupial—Didelphus paraguayensis—a kind of oppossum, also showed an infection index of 4.4%. The trematode found in Minas Gerais is the true S. mansoni and not the variety S. mansoni rodentorum found in the African study.

ENGLAND

Changes in Medical Education.—The council of the General Medical Council of Great Britain puts forward from time to time recommendations on the medical curriculum, its period and scope, the subjects it should include, and their priority. The recommendations carry great weight and are observed by the medical schools and examining authorities. At its last session the General Medical Council considered whether the recommendations it made in 1947 required revision. It has in the meanwhile invited observations and suggestions from interested bodies. A committee of the Royal College of Physicians was

recently set up to inquire into the methods and principles of medical teaching and the medical curriculum. It reports (Royal College of Physicians Committee on Medical Teaching, Second Interim Report, 1955) that several changes have occurred in medical education and practice that must be taken into account in designing future curriculums. Present-day students, many of whom are supported from public funds and by scholarships, specialize early and put examinations first. Compared with their forerunners many students now start medicine with less cultivated minds. Changes have also occurred in the teaching staffs of the medical schools. Teachers, although more numerous, devote themselves to a specialty and lack the breadth of knowledge of the older clinicians. The student does not get the experience he formerly got through apprenticeship to an all-round clinician. Some teaching hospitals rarely treat common diseases and emergencies and have little contact with the community and social life. The growth of "clinical science" has made the staffing of preclinical departments difficult. Physiologists and pharmacologists can often find sufficient scope in clinical studies without teaching in preclinical departments. The report states that although the medical student has practical training in all branches of medicine, the experience he gets is insufficient to enable him to practice any of these branches when he qualifies. He will in fact be discouraged from practicing surgery, anesthetics, psychiatry, or other specialties at anything above an elementary level, unless he undertakes prolonged postgraduate study. Further, there are changes in disease. Some diseases are growing rarer, and new ones, particularly occupational, are being recognized. Social changes affect medicine. There are more old people and more suffering from mental disorders. In the past changes in medicine and medical practice have led to the student being taught new subjects and new techniques without removal of the old ones. "With the growth of knowledge, he has increasingly been offered more than he can digest, and all too often his response has been to form a habit of amassing facts instead of absorbing them—preparing for his examinations rather than for his work as a doctor. The harm thus done to medical education will continue and increase until curricula are deliberately redesigned to provide a basic rather than a comprehensive training for medicine."

In the past the General Medical Council has influenced the teaching of medicine by pointing to deficiencies in the curriculum. The committee thinks that this is not enough. The mass of medical knowledge has become so bewildering that there is more need than ever for the medical student to acquire a grasp of essentials. He should be learning less but understanding more. Now that many clinical teachers are specialists, the traditional training of learning by apprenticeship to a consultant of wide knowledge and experience is in danger. Medical training must be a continuous educational progress in which the curriculum is conceived as a consecutive whole. The committee deprecates the lack of general education and culture of the modern medical student. This is attributed to early and excessive specialization at school because of the high standards of the premedical examination. This examination includes more information than is necessary as a basis for medical study. Likewise, preclinical training is far too detailed and not sufficiently integrated with clinical studies. Faced with a mass of factual information, the student fails to develop the processes of thought and judgment. In the clinical period apprenticeship to a general practitioner is being replaced by multiple appointments in special departments. These tendencies are aggravated by the final examination, which dominates the student's work and thought. He concentrates on memorizing facts that may be asked for in the examination. High failure rates create further anxiety and promote cramming in the library at a time when the student should be learning from experience in the wards and outpatient clinics. In the past, with a curriculum that was not overloaded, the conscientious student, properly selected, could expect to pass. It is regretted that subjects that logically and in practice are closely integrated should be taught as separate disciplines. Although the General Medical Council has always considered that all medical schools should retain their individuality, its recommendations have come to have the force of regulations and the medical curriculum is now governed by the rigid examination system. There is a strong desire to see a reduction in the scope and precision of the recommendations. An American observer said that in the past 10 years no country has produced so many wise reports on the improvement of medical education as has Great Britain, and no country has done so little about it. A change is needed by which medical schools may become free to experiment in medical education radically and individually. The scope of the experiment is great in England because there are many small schools. There is much dissatisfaction with the effects of the existing examination system. The General Medical Council could still maintain effective control, as required by statute, but in a way different from the present control, if more autonomy were given to the medical schools. It would still exercise control by inspection to preserve minimum standards.

Tuberculosis Conference.—The fourth Commonwealth Health and Tuberculosis Conference organized by the National Association for the Prevention of Tuberculosis (NAPT) was held in London in June. The Duchess of Kent, president of the NAPT, presented the Philip medal to Dr. P. V. Benjamin, technical adviser on tuberculosis to the government of India and president-elect of the International Union Against Tuberculosis. This was the first award of the medal, which is being given for outstanding services against tuberculosis, in honor of Sir Robert Philip, founder of the first tuberculosis dispensary. The Minister of Health told of the marked reduction in the last 40 years in the death rate from tuberculosis and of the 70 units for mass radiography operating in England and Wales, or about twice as many as were operating in 1948. About 15 million people, 95% of whom were found to be completely clear, have been thus examined. The proportion found to have active tuberculosis was 3.3 per thousand of those examined. Although we can draw encouragement and inspiration from these figures, we must not allow ourselves to draw satisfaction from them while they remain at those levels.

Dr. H. G. Trimble of Stanford University, California, said that both tuberculin testing and x-ray supplement each other as screening procedures. Tuberculin testing is a well-documented scientific procedure. It is the only test that tells what persons have been infected, in contrast to x-ray or sputum examination, which may show who actually has the disease. Tuberculin testing is important as a case-finding method in areas of low incidence of tuberculosis. In areas of high incidence, as a case-finding method it is of little value, although it may be important in an individual patient as a diagnostic measure. Sample tuberculin testing in any area may effectively evaluate the progress made in the application of other well-known epidemiological procedures. As regards x-ray, a roentgenogram is only a shadow, and we should not attempt to make definite diagnoses on the basis of shadows alone. A mass x-ray survey is an attempt to identify those persons who have roentgenographic shadows suggestive of tuberculosis or other diseases. It is not in itself diagnostic. Further medical study is required to achieve a diagnosis. The members of the committee of the International Union Against Tuberculosis believe unanimously that early diagnosis conditions the success of treatment and the prevention of tuberculosis. It is all the more effective now that we have at our disposal excellent drugs, the speedy application of which increases their effectiveness. The finding of other diseases, especially carcinoma of the lung, may be an important by-product of mass radiography. We should look forward to adequate development of dispensaries in hospitals to make mass x-ray examination a success, but the fact that the problem is defined and made important is reason enough for using mass radiography as an initial case-finding procedure. In the Scandinavian countries this has been carried along, together with BCG vaccination. As tuberculosis becomes less prevalent, efforts must be redoubled to insure its complete eradication.

Salmonella in Sewers.—The presence of Salmonella schottmülleri in sewers is regarded as an indication that an excreter lives in the neighborhood. Investigations by Harvey and Phillips (*Lancet* 2:137, 1955) have shown that this organism may persist in sewers for a long time. They examined samples of Cardiff sewage for over a year and found 11 separate foci of this organism in the city. During an outbreak of paratyphoid spread by cream cakes, and due to a strain of phage-type 1, specimens of sewage from the affected bakery showed the presence of organisms long after all the known excreters in the bakery had been removed. The epidemic was comprised of 92 patients, 76 of whom had eaten cream cakes made by the bakery. Samples of blood were taken from the bakery staff, and two girls who decorated the cakes had positive Widal reactions. After the outbreak had died down, and 10 weeks after the removal of infected persons, the sewage from the bakery was examined and S. schottmülleri was still found. Further information on the survival of this organism in sewers was obtained from an isolation hospital, which admitted a patient with paratyphoid. S. schottmülleri was isolated from the drains for 14 days after the patient's feces were negative. This was in spite of the fact that the patient's stools were treated with 5% phenol for four hours before disposal. As many outbreaks of paratyphoid have been traced to bakery products, the authors make regular weekly examination of the drains from bakeries (with the owners' permission) from March to September and during the rest of the year at monthly intervals. They think that this procedure should provide a reasonable chance of isolating either freshly passed organisms or those that are still living after contamination, during the interval between the placing of swabs in the drains. By this means they hope to identify as soon as possible any excreters employed in bakeries. Positive results lead to immediate examination of the staff.

Combined Immunization.—At the joint annual meeting of the British Medical Association, the Canadian Medical Association, and the Ontario Medical Association, held in Toronto, Canada, in June, Dr. H. J. Parish of London said that at three to four months of age, the child should be vaccinated against smallpox three weeks before any other immunization. In French Equatorial Africa smallpox and yellow fever vaccinations are combined. Smallpox vaccination should be postponed if the child has any skin trouble, such as eczema or a skin condition resulting from a constitutional disturbance. As most deaths from whooping cough occur in the first year of life, protection against this disease should be given early. Many local authorities use combined immunization against whooping cough and diphtheria, and tetanus toxoid can be added with advantage. A large dose (25 Lf) of diphtheria toxoid should be combined with 20,000 million of Hemophilus pertussis and 5 Lf of tetanus toxoid. Three injections of this mixture at monthly intervals are given subcutaneously, beginning at the age of three to four months. A booster dose can be given at one year of age. Immunization with pertussis-containing antigens should not be given if poliomyelitis is prevalent; postinoculation poliomyelitis is more likely after the administration of alum-containing mixtures. In the case of allergic children the initial dose should be small. BCG vaccine should be given to infants only if they have been in contact with known cases and then only after several weeks have elapsed after smallpox vaccination. The repeated use of BCG vaccine may interfere with other immunizations. In Great Britain immunization against diphtheria with alum-precipitated toxoid or aluminum phosphate precipitated toxoid is recommended by the Ministry of Health when the child is 8 to 12 months old, because infants have a congenital immunity in the early months. Combined diphtheria-pertussis immunization may be deferred until the end of the first year. If children were "called up" at this age, those who had had primary immunization previously could be given a booster dose and the others could be given their primary course. Record cards should be kept for all children. Further booster doses can be given at three and five years. For diphtheria, booster doses, or primary courses in the case of the nonimmunized, should be given when children begin school. Dr. J. M. Mather, Vancouver, British Columbia, Canada, said mothers wanted number of injections to be as few as possible, and he favored triple antigen. It is better to treat tetanus if a possible exposure occurs, with a booster dose of toxoid than with tetanus antitoxin. As tetanus often follows trivial injuries, all children should be immunized. Whooping cough commonly occurs in schoolchildren, and, as they can infect infant siblings, the latter should be immunized. Booster doses of pertussis vaccine should be given on entering school.

Dr. P. J. Moloney of Toronto said that important laboratory factors were the variation in antibody response in a particular species, variation in the immunizing potency of different antigens, and the influence on the immunizing antigen of associated impurities. The relative efficiency of different antigens can be compared only if the equivalent amounts of antigen (measured as antigen nitrogen) are injected into the same animals and the antibody produced is also assayed. Associated impurities may affect the potency of an antigen by stimulating or by suppressing production of the protective antibody.

Radiotherapy.—At the same meeting Dr. Edith Paterson of the Christie Hospital and Holt Radium Institute, Manchester, said that in the last 15 years the incidence of leukemia had increased, particularly in professional men. In Canada and in the United States the greatest increase was in men of the older age groups, although this was not true of malignant disease as a whole. In the acute type of leukemia the antimetabolite compounds such as aminopterin, Amethopterin, and 6-mercaptopurine give the best results, although they are only palliative. Radioactive phosphorus, Myleran, and triethylene melamine are also used; 6-mercaptopurine is sometimes of value in treating acute monocytic leukemia.

Dr. Owen B. Miller, Toronto, Canada, reported on 100 patients with advanced malignancy into whose pleural or peritoneal cavities he instilled radioactive gold. Progress was assessed from the frequency of aspirations needed. If a patient responded once, there was likely to be a response to a second injection. The best results were obtained in patients with carcinoma of the breast, 50% of whom showed a satisfactory response. Results in patients with abdominal cancer were not so good. Improvement occurred in half the patients in whom the primary site was unknown. Lymphomas showed little response. Gold injections, not to be used on very ill patients, took some time to act. Dr. Walton, Winnipeg, Manitoba, Canada, said he obtained good results in patients with pseudomyxoma peritonei, using radioactive gold with hyaluronidase.

Etiology of Rheumatic Fever.—At the same meeting Dr. D. A. Long of the Medical Research Council said that group A streptococci provided the most important clue to the etiology of rheumatic fever. Infection with hemolytic streptococci is followed by the poststreptococcic state of Rantz, which develops into the full rheumatic syndrome. Any known type of this organism can cause the disease within three weeks. It occurs not only in the acute state of bacterial invasion and toxemia, adrenocortical stimulation, and protein catabolism but also during the prolonged subsequent stage of repair. Rheumatic fever also occurs in hyperimmune children. The incidence is low in diabetics, and, according to some, it is associated with hyperinsulinism. Rheumatic fever may be due to bacterial allergy, as is suggested by the presence of hypersensitivity of the tuberculin type to streptococcic allergens and an allergic response by the tissues. As a result of work on guinea pigs, Dr. Long suggested that hemolytic streptococci form an exotoxin that acts synergistically with the allergen to produce tissue damage and that transforms a local response to a systemic one. He referred to Coburn's work on the prophylactic value of egg yolk in rheumatic fever and on the separation of an antianaphylactic substance from its prospholipid fraction. A similar product can be obtained from peanut oil. In small doses it depresses sensitivity to tuberculin in guinea pigs. Dr. Long, however, believes that the antirheumatic effect of egg yolk is more likely to be due to essential amino acids than to the presence of an antiallergic substance.

Cancer of the Cervix.—At the same meeting Dr. J. P. A. Latour, Toronto, Canada, said most gynecologists accept the view of the gradual progression over a period of years of carcinoma in situ to clinically diagnosable cancer. Tissue biopsy as a means of diagnosis is unsatisfactory unless a whole ring of tissue is removed. Schiller's test and colposcopy are of doubtful value in indicating the site for the biopsy specimen. The best method is to examine smears from the cervix, removed by scraping with a wooden spatula (Ayre's method). The variations observed are due to the personal factor in reading the smears. If the smears are positive, diagnosis should be confirmed histologically by removing a ring of tissue and making serial sections. Of 21,895 women screened, 375 had positive smears, although cancer was suspected clinically in only 36. In this series, a total of 145 cases of carcinoma in situ was discovered. Early invasive cancers were found in 73% of 107 women with positive smears. No cancer was found in 34 women whose smears were negative but in whom cancer was suspected clinically. Smears can be mailed from outlying districts to centers where cytological examinations are made. Dr. Malcolm Donaldson of London said that the diagnosis of cervical cancer is easier than getting women to consult their physicians early enough to be cured. Although irregular vaginal bleeding is an important warning sign in women over 40 years of age, it is seldom taken seriously by these patients.

ITALY

Treatment of Pericarditis.—At a meeting of the Medicosurgical Society of Romagna, Professor Paolucci said that there are two opposing viewpoints regarding the surgical treatment of chronic constrictive pericarditis; one favors decortication of the heart extended to the point of liberating the right ventricle and the mouths of the venae cavae; the other favors a less radical intervention (Schmieden's operation), which, although limited to liberating the left ventricle, gives satisfactory results. The speaker preferred the conservative method. From the etiological standpoint, pericarditis, which is more common in patients between the ages of 20 and 30 years, is rarely of definitely rheumatic or tuberculous origin; usually the causative factor is obscure.

Bronchial Asthma.—At the same meeting Professor Serafini said that the difficulties encountered in establishing the most adequate therapeutic regimen for each patient with bronchial asthma arise mainly from the fact that the etiological problem of the syndrome has not been completely solved. This situation has led to a certain skepticism about the therapeutic possibilities, but there are today treatments of undoubted efficacy that make possible the remission of the symptoms in most patients and the disappearance of them for long periods of time in some of the rest. Specific desensitization can be useful, and lately it has undergone some very interesting changes. For example, the administration of minimal doses of allergens has proved useful. A combination of desensitization, antihistamines, and cortisone is also useful. Hypodermic injections of epinephrine must be used carefully because the excess use of sympathomimetic drugs may result in status asthmaticus. The speaker believes that morphine has no place in the treatment of bronchial asthma. Among the other dangers secondary to the administration of this drug is its depressing action on the respiratory center.

Synthetic antihistamines are ineffective, but this does not exclude the histaminic mechanism of the asthmatic attack. The effect of cortisone and corticotropin on the severe manifestations of asthma is always favorable and sometimes dramatic. Of 50 patients with status asthmaticus who were given corticotropin intramuscularly, 80% obtained favorable results; this is not possible with any other treatment. Not recovery, however, but only a temporary remission of the symptoms is obtained. The remission may be partial or total depending on the reversibility of the anatomicopathological alterations that are the basis of the asthmatic syndrome. Hydrocortisone given orally is much more active than corticotropin or cortisone for rapidity of action as well as for decrease in the effective dose and for reduction of phenomena of intolerance. The speaker also found that reactions to morphine, quinine, and sulfonamides are encountered with greater frequency and severity in patients with asthma than in other patients. Therefore, a patient with asthma must be given these drugs with great caution.

Splenomegaly in Infants.—At the same meeting Sega and Gobbi stated that in infants sclerocongestive splenomegaly must be differentiated from chronic infective splenomegaly; granulomatous, hemoblastotic, or hemolytic splenomegalies; and the pure splenic form of giant follicular lymphoma (Brill-Symmers disease). The speakers expressed the belief that sclerocongestive splenomegaly and splenic anemia may have an initial phase characterized pathologically by a hyperplastic-reactive, nonspecific, and fibrillopoietic pulpitis in common. It is not possible to say whether sclerocongestive splenomegaly and splenic anemia are two different diseases or different aspects of the same disease. In treating either condition splenectomy should be performed as soon as possible to interrupt the chain of morbid processes that lead to gastrointestinal hemorrhages.

Cancer of the Prostate.—At the 10th convention of the International Society of Urology in Athens, Professor Sorrentino of Naples and his co-workers reported that hormonal therapy is based on the assumption that the androgens influence the development and growth of prostatic cancer in many patients, suppressing as completely as possible the production of androgens. This can be achieved by castration, which surgically removes one of the main sources of androgens, or by giving estrogens. Some workers favor estrogen therapy alone, but most authors agree that the best results are obtained by combining the two methods. Because castration causes reactions in the adrenals that increase their production of the 17-ketosteroids, hormonal therapy can be rendered more efficient by combining it with adrenal and hypophyseal antagonists. These actions are debatable and dangerous, however, and change the situation little when they are used to supplement estrogen therapy that is no longer effective.

The mechanism of action of the artificial estrogens is not clear; the action instead of being hormonal may be pharmacological or radiomimetic. This hypothesis has led to the concept of treating prostatic cancers with androgens or progesterone but conclusive results have not yet been observed. The fact that some cancers of the prostate are not influenced by antiandrogen therapy suggests that prostatic cancer is not a single entity. Results of the antiandrogen therapy are good in many patients, but they are temporary. This is therefore a palliative method of treatment, not devoid of dangers, and apparently unphysiological. The results of irradiation are only fair. Electroresection may be necessary in treating a complicating urinary retention. Treatment with cytochrome oxidase and the urine factor of Sorrentino can be considered as adjunctive treatments. The treatment of choice is prostatectomy, which should be performed as soon as possible. All men over 50 should be examined periodically to detect latent cancers.

PERU

Congress of Sanitary Engineering.—The first Peruvian congress of sanitary engineering was held in Lima in April. Because of the high incidence of infectious diseases in Peru, due in part to the lack of adequate sanitary and hygienic conditions, it is essential that a beginning be made promptly to correct these deficiencies. The government was urged to take steps to improve the water supply and the disposal of sewage. The congress urged the government to reduce or abolish customs duties on the import of sanitary equipment and to encourage the creation of industries producing materials and chemical products necessary to the achievement of improved sanitary standards. In view of the great waste of potable water in the cities, a tax on excessive water consumption was urged. It was also recommended that the government make a survey of sources of potable water, drainage, hydraulic power, and irrigation requirements of all parts of the country. A study should also be made of the best way to control the pollution of public baths, swimming pools, and seashores used for surf bathing. Greater cooperation between the departmental sanitary units and the sanitary and hygienic departments of the cities is needed. To attain this purpose a sanitary engineer or any other functionary of the sanitary unit of a region should be named member ex officio of the municipal department. Organizations in charge of the fight against insect vectors of disease were advised not to rely exclusively on the action of insecticides on adult forms but to include in their programs the use of appropriate larvicides.

SWITZERLAND

Pregnancy and Cortisone.—Workers administering corticotropin or cortisone to gravid laboratory animals have regularly observed the following bad effects on the fetuses: abortion a few days after the start of treatment, birth of a small fetus that is partly resorbed or completely macerated, neonatal death of the young, or congenital anomaly. More or less prolonged courses of cortisone therapy, however, have been administered, apparently without harmful effect, to pregnant women with acute polyarticular rheumatism, pemphigus, herpetiform dermatitis, or threatened Rh sensitization with danger of erythroblastosis fetalis. There has been up till now no reported case in which a patient received cortisone uninterruptedly throughout a pregnancy that was normal in every way but after which the baby showed signs of acute transitory hypoadrenalism. A 28-year-old woman had severe chronic rheumatic polyarthritis. She could not tolerate gold salts and had therefore been maintained for more than three years on a daily dose of 50 to 75 mg. of cortisone. A pregnancy occurring during the period of treatment produced no improvement in the rheumatism, as is usually the case under such circumstances. The patient's disease remained the same, and no change in dosage could be made. Prof. G. Bickel, head of the University Medical Clinic of Geneva, administered a dose of a little over 16 gm. of cortisone during the nine months of pregnancy with no unfavorable effects on the pregnancy, delivery, or postpartum period. The baby was born at term and weighed 3,650 gm. (8 lb. 1 oz.). He was well formed and seemed to be in perfect health, but transitory episodes of hyperglycemic coma occurred, which were swiftly corrected by combined administration of glucose, cortisone, and corticotropin. The baby's symptoms resembled those seen in patients maintained on cortisone therapy that is abruptly withdrawn. An experiment was conducted in 10 pregnant white rats that received daily intramuscular injections of 3 mg. of cortisone throughout gestation. Pregnancy and delivery were normal in every case, but the adrenal glands of the young were definitely smaller than those of young from control animals.

Four Years' Experience with the Betatron.—The betatron does not emit continuous x-rays. In correlation with the phases of alternating current, it gives 50 trains of waves of 10 microseconds each per minute. The biologically active secondary electrons formed at this time reach a significantly greater distance than those of roentgen rays at 200 kv. Furthermore, they are for the most part propagated parallel to the primary ray. There is thus greater deep activity. At the annual meeting of the Swiss Radiological Society at Baden in June, Profs. H. R. Schinz of Zurich and A. Zuppinger of Bern reported the results obtained with this treatment. Schinz irradiated 66 patients with carcinoma of the esophagus. Dramatic, more or less lasting, improvement occurred in 15; longest follow-up in this series was 30 months. He irradiated 37 bronchial carcinomas; 17 patients obtained characteristic subjective improvement. Of 27 patients with carcinoma of the urinary bladder, 2 of the 8 with inoperable lesions have survived symptom-free for two and a half years. Another 35 patients with carcinoma of the uterine cervix, 15 of whom had had a prophylactic operation, were treated; 12 of these have survived without symptoms. Schinz also obtained good results in carcinomas of the body of the uterus and of the ovary. With the exception of the patients irradiated prophylactically following operation, most had far-advanced inoperable lesions. The betatron is thus shown to give results that 200 kv. irradiation could never achieve in the same proportion. Zuppinger obtained excellent results in the irradiation of brain tumors and lesions of the mouth, the maxilla, and the pharynx. Even carcinoma of the stomach benefits from this therapy. The use of betatron irradiation before gastric resection might produce better results in this dangerous form of cancer. The Swiss radiologists consider that treatment with the betatron represents a significant step forward in radiation therapy.

Idiopathic Edema from Sodium Retention with Hyperaldosteronuria.—Since 1949 Prof. R. S. Mach, head of the University Therapeutic Clinic of Geneva, has followed a certain patient. Every time she ingests more than 4 gm. of sodium chloride a day she has weight gain, generalized edema, headache, disturbances of vision, and papilledema. She has no indication of renal, cardiac, or hepatic disease to explain the appearance of the edema. Her syndrome resembles that caused by desoxycorticosterone. Because of this, Mach and his co-workers examined her urine to see if she had an excess of aldosterone. This proved to be the case in three successive tests. This constitutes a new pathogenetic possibility for certain hitherto unexplained edemas. The aldosterone found in the urine was 10 to 15 times greater than that in normal subjects. The elevation was present both in periods of salt-restricted diet and in those of salted diet. The overproduction of aldosterone in this patient, evidenced by the urinary findings, would seem to account for this syndrome. Besides the aldosteronuria that accompanies the lipid nephrosis of cardiopathy, i. e., secondary aldosteronuria, there would seem to exist a primary aldosteronuria of which overproduction of the hormone is probably the cause. In addition to the syndrome reported by Mach, aldosteronism can manifest itself as a potassium depletion syndrome with paralysis.

Pulmonary Tuberculosis, Diabetes, and Cortisone.—Although extreme caution is essential regarding the use of corticotropin and cortisone in patients with infectious diseases, especially tuberculosis, tuberculosis and most other infectious diseases are not aggravated by these agents if a suitable chemotherapeutic agent is administered at the same time. G. Bickel and M. Chauvet of the University Medical Clinic of Geneva recently treated a 72-year-old woman with diabetes of 15 years' standing who had severe caseous tuberculosis in the fall of 1954. The disease evolved toward the cavitation despite combined therapy with streptomycin, isoniazid, and aminosalicylic acid but was rapidly controlled by an intensive course of cortisone therapy (6.75 gm. in 62 days). Not only was the patient in a desperate state, having been unconscious for several days, but also her caseous tuberculosis had developed on a background of diabetes. Cortisone is known to aggravate that disease, but in this case it caused no more than a temporary need for more insulin, which situation corrected itself in less than two weeks after cortisone therapy was stopped. Thus it can be concluded that diabetes, even when associated with severe tuberculosis, does not constitute a formal contraindication to the use of adrenal corticosteroids.

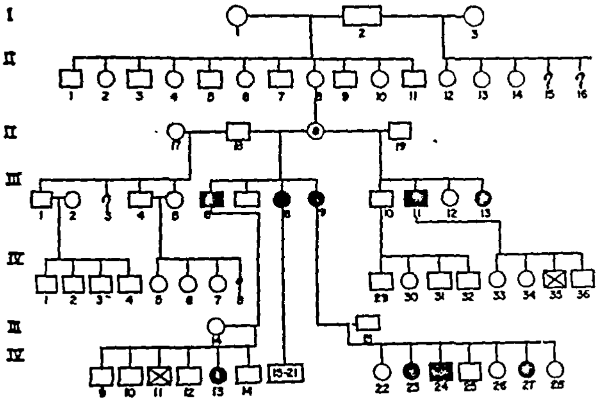
Photoallergic Eczema.—At the annual meeting of the Swiss Society of Allergy in Bern in June, W. Burckhardt of Zurich spoke on the reaction produced by new laundering products containing optic illuminations that, through fluorescence, transform invisible ultraviolet into a blue light, so that the washing appears "whiter than white." A cleaning woman had acute eczema of the face and hands after using such a product. The usual skin tests with the washing compound were negative. On irradiation with visible light and ultraviolet rays of a patch of skin treated with the product, a strong eczematous reaction resulted. This reaction was not reproduced in control subjects, showing that the patient had an allergic hypersensitivity to the combination of optic illuminations and light. Photoallergy was first observed after the administration of sulfonamides. Recently similar phenomena have been observed after administration of chlortetracycline, aminosalicylic acid, and *p*-aminobenzoic acid ester.

Health Insurance in Geneva.—Switzerland is one of the few countries of Europe to fight for free, private medicine that is neither nationalized nor institutionalized. In Geneva, until a few months ago, physicians were not held to a fixed fee, but in view of social necessities, the physicians of Geneva signed an agreement with the Federation of Health Insurance Companies, with the result that only those physicians who signed are allowed to take care of insured patients. Free choice of physicians is guaranteed to insured patients except in cases of hospitalization. The physician is free as regards diagnosis and treatment, except insofar as he must use the most economical means possible. The patient's confidence is protected. A fee has been fixed. It was accepted by the physicians, although they could hardly think of it as a fee adapted to the present cost of living (consultation, $1.25 and house call, $1.85). The treating physician may send a supplementary bill to an insured patient if he believes that the latter is in a position to pay it.

CORRESPONDENCE

IMPORTANCE OF EARLY DETECTION OF GLAUCOMA

To the Editor:—The urgency of early diagnosis of chronic simple glaucoma stems from the fact that good therapeutic results are expected in early cases. By contrast, late cases invariably have sustained irreversible visual loss. The necessity for routine screening examinations is explained by the asymptomatic nature of chronic simple glaucoma. Aptly termed "the thief in the night," glaucoma stealthily encroaches on visual field and acuity, with this loss detected irrecoverably late by the victim. Many physicians have the misconception that glaucoma is an unimportant, rather rare, acute disease, readily recognized by the painful, hard, red eye. These are the characteristics of acute glaucoma. Far more common is chronic simple glaucoma. Thirteen per cent of all blindness reported in North America and Western Europe by Sorsby is due to glaucoma (*Brit. J. Oph'h.*, monograph supplement 16, 1950). Mass-screening procedures (*J. A. M. A.* 56:933 [Nov. 6] 1954) indicate that about 2% of Americans over the age of 40 have chronic simple glaucoma, most of these being early, unrecognized cases. The age of onset of blindness from chronic simple glaucoma is, on the average, between 60 and 65 years (*Canad. M. A. J.* 66:563, 1952). Since the average life expectancy has increased from 45 to 65 years during the past half century, many more people are now surviving to an age where they may be expected to become blind from glaucoma. This increased life expectancy is the prime reason why the physician must be increasingly alert for the detection of chronic glaucoma. Current statistics from the state of Ohio number the known totally blind at 13,500. Of these, 1,320 (about 10%) were blinded by glaucoma during the 10 year period 1945 to 1955. The cost of this blindness is enormous, $2,733,000 being spent in caring for the blind in Ohio in 1954. Economic loss due to the reduced productivity of these blind thousands is inestimable. Clearly, glaucoma has established itself as a major cause of the suffering and economic loss due to blindness.



Glaucoma pedigree showing dominant inheritance.

The early diagnosis of glaucoma can be made only with the help of a high index of suspicion. This suspicion should exist when the following conditions are present. 1. The patient is over 40 years old. Two of every 100 people over 40 years have chronic glaucoma—an incidence similar to that of diabetes mellitus. 2. A family history of glaucoma exists. Being a dominantly inherited characteristic (see figure), glaucoma should be included in the family history just as are diabetes and hypertension. Every ophthalmologist knows of cases of glaucoma detected simply by taking a family history. More than one case of glaucoma in a family can be found by questioning in 13 to 25% of patients with chronic simple glaucoma. 3. The anterior chamber is shallow. Simply examining the anterior chamber depth with a flashlight can provide a valuable clue suggesting increased susceptibility to acute glaucoma. Not only patients with glaucoma but also their siblings and children have been shown to have significantly decreased anterior chamber depth. 4. There is unexplained aching of or about the eyes. This is a vague symptom with many causes, common among which are refractive error, sinus inflammation, and psychogenic factors. Since such discomfort may be the only early symptom of chronic glaucoma, it should not be dismissed without investigation. It is not to be inferred that glaucoma can be diagnosed by ocular discomfort. In one series (*Canad. M. A. J.* 66:563, 1952) of glaucoma blind, only 7% had had an acute attack, 24% denied ever having any ocular pain, and 69% had experienced transient episodes of aching and occasional redness of the eyes. 5. There is increased intraocular pressure. In chronic glaucoma the elevation of intraocular tension is slight and cannot be detected reliably by finger tension. Only by routine use of the tonometer in patients over 40 years old can the early diagnosis of chronic simple glaucoma be made. Such routine tonometry is the practice of most ophthalmologists. Unfortunately much of the population is not reached by ophthalmologists, and tonometric screening will have to be done by the general physician or in mass surveys in order to be truly effective. For many years the Ophthalmological Foundation, Inc., New York, has advocated the practice of routine tonometry by the general physician, to be initiated at his request under the guidance of his local ophthalmologist. Tonometry performed by the medical profession would be expected to be a more permanent answer to the glaucoma problem than the mass-screening procedures.

The glaucoma project at Wright-Patterson Air Force Base may be cited as an example of what may be accomplished by a mass-screening survey. During a five day period, 4,013 of the civilian employees underwent tonometric screening. Initial tonometry was performed by nurses, using a Schiøtz tonometer with 7.5 gm. weight. Three hundred fifty-two employees were found to have an elevation of 28 mm. or higher. On recheck by the ophthalmologist, 71 of these 352 were confirmed as elevated. It was assumed the remainder were false positives, although diurnal variations in tension cannot be excluded. These 71 patients were referred to the ophthalmologist of their choice with an explanatory letter. The report of the examining ophthalmologists are tabulated as: confirmed as glaucoma, 37; not confirmed, 25; and no report received, 20. As a result of this survey, therefore, 37 previously undiagnosed cases of glaucoma were detected and placed under proper medical supervision. Furthermore, all persons participating in the survey were introduced to the fact that glaucoma exists as a preventable cause of blindness. Late diagnosis of glaucoma is undesirable because vision already lost is irreplaceable. Nevertheless, proper miotic or surgical therapy will reduce the rate of further progress (except in far-advanced cases). The physician should, therefore, be cognizant of the late signs of glaucoma, including glaucomatous cupping of the optic nerve, visual field loss, decreased visual acuity despite glasses, and spontaneous retinal arterial pulsation.

HOSPITAL PATIENT

To the Editor:—I should like once again to call attention to my letter published in The Journal, March 5, page 842, entitled "Missing Hospital Patient." Since publication of this letter I have received numerous replies, from California to Wisconsin, concerning previous hospital admissions of Mr. Leo Lamphere. After escaping from the Iowa Mental Hospital, Lamphere made his way to Wisconsin. He stopped at several hospitals in Illinois, always presenting with hemoptysis and thrombophlebitis and always signing himself out before definite diagnosis could be made. He finally made his way to the Wisconsin State University Hospital, where his behavior paralleled that at the State University of Iowa Hospitals. He is reported to have slashed his femoral artery with a razor. He was transferred to the State Hospital for the Criminally Insane at Waupun, Wis. I wrote to this institution giving them the facts about this extraordinary patient and received no reply. On writing to them again I learned, to my dismay, that the patient had been discharged on June 8, 1955. From Waupun he proceeded to Ann Arbor, Mich., and was hospitalized on the surgical service there. I believe he was discharged from there about Aug. 11, 1955. In addition to his activities as described above, the man has been a professional claims collector from insurance companies. Since May, 1954, this man has made his way from hospital to hospital across California, Oregon, Montana, South Dakota, Minnesota, Iowa, Illinois, and Wisconsin. He was also hospitalized at Salt Lake City, Utah, where his inferior vena cava was ligated. He apparently never does anyone physical harm but is a definite economic liability to the medical profession. The source of his hemoptysis, which may be self-induced, remains a mystery.

FOREIGN FELLOWSHIP

To the Editor:—A fellowship in pulmonary physiology for foreign doctors, particularly those from the United States, is now available at the Pulmonary Physiology Laboratories of the University of Nancy Medical Center, Nancy, France, under the direction of Dr. Paul Sadoul, associate professor, University of Nancy School of Medicine. This fellowship runs for a minimum of 6 to a maximum of 10 months, commencing August, 1955, to June, 1956. It pays 30,000 francs a month and offers extremely reasonable eating facilities at the university restaurants. The work consists of both pulmonary function examinations on patients and experimental research work on animals in the newly constructed basic science building. Physicians with a cursory knowledge of pulmonary physiology and some background in chest diseases should find this fellowship extremely interesting. I have just returned from six months' work in this setup and found it most stimulating. Some knowledge of the French language is preferable, and with a meager background in French one should be able to converse well enough to participate in all the activities after the first month. Dr. Sadoul has studied pulmonary physiology in the United States in the laboratories of the University of Rochester, New York, and also at Bellevue Hospital, New York. He is one of the recognized authorities of France in this field. The University of Nancy Medical Center is well known for its contributions in the field of pulmonary disease under the guidance of Professor Simonin. The town of Nancy is in the Province of Loraine and closely situated to the borders of Germany, Belgium, Luxemburg, Holland, and Switzerland and is ideally located for short visits into these countries. I highly recommend this position to anyone interested and suggest that they write directly to Dr. Paul Sadoul, Hospital Villemin, Nancy, France.

NEW USE FOR OLD GARMENTS

To the Editor:—Having been the victim of intermittent arthritis for over 23 years, I have found one or two simple measures that have proved helpful. Shoulders and knees have been the joints of predilection. Here I found protective covering beneficial. For shoulder protection the upper section of an old shirt or undershirt may be used. That portion of the garment below the first or second button is cut off entirely, and the upper portion is worn as an extra garment. The sleeves may be cut off above the elbows if the elbows are free of pain; otherwise below the elbows. The type of shirt used should be determined by the climatic conditions and the environment: flannel in cold weather and lightweight shirts when the weather is unduly warm At night this garment may be worn under the pajamas. During the day for minimal protection, as in a siesta, the protective garments only will suffice. For the knees I formerly wore thick woolen knee protectors, purchased in department stores or especially knitted for the purpose. In driving a car I have been compelled, at times, to use a small woolen blanket. The wool knee protectors proved too stiff, too tight, or too hot. Rubb knee protectors do not permit the perspiration to evaporate a are almost invariably uncomfortable. Now I simply use for fitting elastic socks from which the foot has been cut awa The upper end fits firmly and well and affords all the prote tion desired, even in long automobile journeys during cold a inclement weather. Old elastic form-fitting socks may pro equally valuable for elbows, ankles, or wrists. The weight of t socks used should be determined by the climatic conditio Before having a patient go to the trouble and expense of buyi special articles, these simple measures should be tried.

Hospital "Eugenio Espejo"
Quito, Ecuador, South America.

MISCELLANY

OUR AMERICAN WAY OF LIFE

Herbert Hoover

Following are excerpts from an address "Our American W of Life" given by Herbert Hoover on the occasion of his 8 birthday celebrated by the state of Oregon at Newberg, Or on Aug. 10, 1955.—ED.

It is indeed a great honor to have been invited by the Go ernor and Legislature of Oregon to spend my birthday on t scenes of my boyhood. I was brought here 70 years ago to li in the family of my Uncle Dr. Henry John Minthorn, a countr doctor. My activities hereabouts did not make any great tran formation of human society. But something else does warra the restoration and dedication of this cottage. That is expresse in the plaque you have put upon it. "This House was the Hom of Dr. Henry John Minthorn, a beloved physician in this Com munity." I am honored to be mentioned on the plaque. Wh you have done here is to pay a tribute to all the pioneerin country doctors of our Nation. There are thousands of cottag in this land which should be marked with plaques recallin their devotion.

John Minthorn was one of those devoted men. He was bor 110 years ago in the Quaker faith. He practiced his healin profession mostly in this State for 45 years and he lies burie in this village. As a boy he witnessed the underground in th Midwest, where during the nights the Quakers transporte Negroes escaping from slavery northward to the freedom o Canada. He reached maturity during the Civil War and joine the Union Army out of conviction in the matter of huma slavery. Quaker pacifism did not extend into that area of though Returning from the War, he graduated from the medical school of Iowa, of Pennsylvania and of Ohio. He was equipped wit the full medical skills of his day. In those early days the patient often could not pay the doctor, and Uncle John at interval in his life taught school or did missions to the Indians for th Government in order to make ends meet. But even along wit these duties, he was still the incarnation of the country doctor

Let no one think that the country doctor of a generation ago was not a skilled man. Without the amazing modern aids of diagnosis, he was a sure diagnostician of the major ills of mankind. Without anti-biotics, without vaccines—except for smallpox—without vitamins, without the X-rays and fluorescent photographs of your innards, the country doctor did healing in an amazing degree. Hot towels and cold towels were substituted for aspirin and codeine. No doubt Mother Nature used more pain in her healing processes. But statistics show that a host of his charges reached old age safely. But beyond his healing art, the country doctor did far more. He instilled the community with the common sense of preventive medicine. He brought sympathy, spiritual strength and courage to the troubled patients. He healed their spirit. He brought their babies into the world. He piloted the youngsters safely through their measles, chickenpox and mumps without the aids of modern medicine. His major word of comfort was "You cannot have it twice." He gave counsel and courage to the young and helped them to find a job. He was their life-long friend. He was the confidant of the family and he healed many a family conflict. He was a leader in the affairs of the community.

The plaque on this cottage is a tribute to a great profession which has made much of the spiritual backgrounds of the American people. The species of the country doctor is not extinct. With urban life, paved roads and the automobile, he has changed his name to that of the family doctor. He is better equipped to fight disease and accident, but the family doctor has the same qualities of moral strength, friendship and family guidance as of old. And it is the family doctor's knowledge that these needed moral and spiritual services could not survive socialized medicine that leads him to fight it at every turn. And this is no disparagement of the great specialists who daily save the lives of thousands of our people. But America needs more family doctors.

This occasion also recalls the part of pioneer men and women in the Northwest, of their staunch fidelities to the ideals of free men and the moral and spiritual life with which they endowed our generation. Once upon a time it was the custom of our people to gather on the Fourth of July and someone would read the Declaration of Independence with the Stars and Stripes in the background. Someone spoke on freedom and the greatness of America. It was in this village that I first had that inspiring experience—and from Dr. Minthorn. In order to do our part we, the oncoming generation, packed a drain tile with appropriate gun powder, tamped both ends hard with clay, and fixed a fuse. The fuse was short—and tile proved more powerful than we expected. Dr. Minthorn was busy for hours picking pieces of tile out of the skins of small boys. He engaged in no reprimands. Dr. Minthorn and his generation had deep convictions on the American way of life. Their fathers were the sons of men who had fought the war for American Independence. They themselves had fought the Civil War to free the slaves. Their lights along the way of American life were the Declaration of Independence, the Constitution, Washington's Farewell Address and Lincoln's Emancipation Proclamation. They held that the function of the Federal Government was to safeguard the individual freedoms and trust to the initiative of men to generate progress. Probably some will say that the recalling of those times, of those men, and of those beliefs is an expression of longing to go backward in American life. No sane person ignores the shifting scene on our national stage. But do not forget the many thousands of Dr. Minthorns and their wives who sustained and enlarged the spiritual forces which give the impulse to our way of life today.

During the last score of years our American way of life has been deluged with criticism. It comes from our own people who deplore our faults and genuinely wish to remedy them. Among these I myself have joined because of my anxieties over mistaken policies and especially the influence of Karl Marx on our way of life. Criticism comes daily from the habit of our political parties to deplore the opposition. It arises from the forthright refusal of the American people to wash their dirty linen in secret. It comes from our love of sensational incidents where villainy is pursued by law and virtue triumphs. And it comes from the fuzzy-minded totalitarian liberals who believe that creeping collectivism can be adopted without destroying the safeguards of free men. It comes bitterly and daily from the Communists at home and abroad who would overthrow our American system. And it even comes from free nations whom we have tried to help. Altogether, if we look at the criticisms alone, we seem to be in a very, very bad way and engaged in our decline and fall. In all this clamor we might occasionally mention something good about ourselves. We could point out that our American way of life has perfected the greatest productivity of any nation on earth; that our standard of living is the highest in the world. We could point to our constantly improving physical health and lengthening span of life. We could point out that the mechanical genius of our people has, by millions of labor-saving machines, taken the sweat from the backs of most of our people. In the governmental field, we could suggest that our supposedly decadent people still rely upon the ballot and the legislative hall to settle their differences without a secret police with slave camps. In the cultural field, we could point out that with only about six percent of the world's population we have more youth in our institutions of higher learning than all the rest of the world put together. We could probably enumerate more libraries and more printed serious words than all other 94 percent of all the people of the earth put together. On the moral and spiritual side, we have more hospitals and charitable institutions than all of them. And we could suggest that we alone, of all nations, fought in two world wars and asked no indemnities, no acquisition of territory, no dominations over other nations. We could point to our advancement of the spirit of compassion. We could prove it by the billions of dollars we have made as gifts to save millions from famine and governments from collapse.

Much as I feel deeply the lag in giving full equal chance to our Negro population, yet I cannot refrain from mentioning that our 14 million American Negroes own more automobiles than all the two hundred million Russians or the three hundred million Negroes in Africa. All of which is not boasting, but just fact. And we could say a good deal more. What does all this mean? It means that freedom of mind, of spirit and initiative still lives in America. It means that our people are strong in religious faith. Here alone are the open windows through which pours the sunlight of the human spirit. Here alone, even with all its defects, is human dignity not a dream but an accomplishment. These ideals of freedom and religious faith guarantee there will be no decline and fall of American civilization. Therefore we should lift our eyes unto the hills from whence cometh our help.

BUSINESS PRACTICE

This is the sixth in a series of articles by these authors on various phases of business practice.—Ed.

HOURLY-RATE BASIS OF FEES

Chester Porterfield, San Francisco

and

Geoffrey Marks, Seattle

In the preceding article in this series,[1] we outlined certain ethical considerations for establishing fair medical fees. We saw that a fair fee to the patient would "not generally require him to pay more than other patients are charged by that physician for a comparable service." To the physician, a fair fee was presented as "in proportion to the time and energy that he applies to the particular service." In expanding this concept, we stated: "The hourly-rate approach also meets the requirements of fairness to the physician, in that he is assured of receiving a fairly

definite income from every working period, no matter what service he performs, since all his fees are based on the same hourly rate." The foregoing statement has frequently produced vigorous objections from some of our medical friends and clients, who have taken exception to the implications of commercialism that they feel it would impose. Some of them approach the problem from the mystical basis of the physician as healer and argue that the emotional bond between the physician and patient will be shattered if the question of cost is permitted to enter into the picture until the healing efforts have been accomplished. Others object from a more modern viewpoint, that of the physician as medical scientist, on grounds that the scientist's essential objectivity in mobilizing all diagnostic and therapeutic measures at his command must not be hampered by limitations of time or cost.

To both factions, we can only point out that the hopes they apparently voice for an "ideal" atmosphere in which to practice medicine are not presently attainable in our society. In effect, and carried to the logical extreme, their visualizations of this ideal lead them inescapably to the thesis that all health-protective efforts should be financed by society as a whole, which is the fundamental basis of the "socialized medicine" that most seem to fear as the death-knell of personal initiative. (We would only observe, from studying the ever-increasing sphere of public health responsibilities in medicine over the past 50 years, that this apparent encroachment on the field of private practice has occurred through a space of time when the healing potential of private physicians has itself expanded to an even greater extent.) To return to our fundamental argument, we can state it no better than in the ancient Talmudic injunction to the physician that he "be worthy of his hire" by establishing a proper compensation for the services he renders.[2] This proper compensation for valuable services honestly rendered is then our goal to determine, and we have stated our views [1] that the physician's own time spent on the service comes as close to being a fair measure for determining its cost as has been devised up to this present.

HOURLY-RATE BASIS

In order to establish an hourly-rate basis of fees the following arithmetical quantities must first be determined by the physician, and he and his staff must be prepared to devote some time and effort to their derivation.

What Is This Physician's Annual Net Income Objective?—He cannot reply, "as much as possible!" On the hourly-rate basis there is theoretically no limit to how much a physician may earn; in practice, the higher his financial ambitions lead him, the more intensively he must educate his patients to accept his services as worth the higher fees that his ambitions demand. Carried to the extreme, a physician's financial ambitions may lead him to setting such high fees as actually to defeat his goals. The competitive factor, which we customarily decry,[1] operates here to monitor ambition; patients will either find other physicians in the community performing comparable services at lower cost, or will do without the service entirely if they know it is completely beyond their means. The physician who might thus set an exorbitant value on his efforts will eventually find himself "priced out of the market" in one of the traditional applications of free enterprise economy. In this fashion society at large can enforce upon physicians the fact that some are more capable in their profession than are others. But no physician can achieve his own proper level of fees, wherever it may be, unless he selects that level and strives through his own persistent efforts to attain it. The vague desire to "make as much as possible" has led to the abuses that have destroyed the validity of fee schedules currently followed. In summary, the physician's net-income objective must be established realistically.

How Many Productive Hours Annually Can the Physician Spend with Patients?—We generally define "productive hours" as hours spent in the presence of patients. Unless he holds an extremely remunerative teaching, consultative, or hospital appointment in addition to his private practice, the physician's income must be derived from the time spent with his own patients. He frequently devotes many unremunerated hours to clinic work, teaching, writing, research, postgraduate studies, and other professional activities. If he is to earn a fair living, he must be paid for these hours, in some way, that do not carry any or adequate pecuniary reward. His problem here can solved by ignoring these hours in his computations and relati his "desired income" to his productive hours, as defined. Li the man who desired an unusually high income, the man w wishes to devote an unusually high proportion of his time such unremunerative professional activities as the above will fi that he must set higher private fees in order to realize his pe sonal objectives and hope these activities may help to bri recognition that his services are worth his higher personal fe

What Are Various Services Performed by the Individual Ph sician in His Field?—Earlier in this series,[3] we cited the "a vantages of inclusive fees." In preparing his own catalogue services, he should consider this approach, and include ma hitherto separate services under such inclusive heads, establis ing them as true therapeutic entities, not merely grouping the arbitrarily in order to avoid too many categories. In this co nection we would repeat: "In setting up and applying his p sonal schedule of fees, the physician must remind himself th there is no such thing as an office visit. He may examine, dia nose, consult, perform or prescribe treatment, give educati in therapy, reexamine to confirm diagnosis, or determine t progress of therapy; all are different services that individua or in combination may carry different fees." [4]

What Is the Average Time Devoted in Performing Each These Services?—In arriving at these service/time averag through analyses of past performance, the sampling used shou be as extensive as possible. We recommend consideration of minimum of 20 cases in each category, but 50 to 100 see preferable, because the broader the sample the fairer will be t fee finally established. Two principles are involved here. T first, an elementary statistical concept, is that the total ti consumed by the 40 previous cases (including those that we smoothly and demanded a minimum of time and also those th were protracted either by atypical response to therapy, id syncrasy, or unusual demands on the part of the patient) w total very nearly the amount of time that will be consum by the next 40 cases in the same category. The second princip basic to insurance underwriting, is that all patients will pay t same fee for the same service, despite the possibility that service may require an average of 15 hours, with most ca demanding only 13, but some as much as 25 hours. In t example, while it is true that the more fortunate patients pa on a $20 hourly-rate, $40 more than they might have on a "p visit" basis, the patient whose problem requires 25 hours is n penalized by having to pay an extra $200 for the extended me cal care, as well as usually experiencing higher hospital expen and a probable greater loss of income.

Excellent success with this approach was demonstrated to by a group of general practitioner clients whose custom it h previously been to charge $350 for cesarean section. They in cated that in their experience they had rendered this additio service in about one obstetrical case in 50. Therefore, in arrivi at their new inclusive obstetrical fee, we included $7 to co delivery by section, if it were required. In other words, und standing that there would be "no extras," every patient w happy to pay an unidentified part of an inclusive fee as insu ance against the possibility of having to pay a far greater su if she should turn out to be the one in 50.

Closely associated, in effect if not in logic, with this insuran principle, is the powerful psychological factor that patients cu tomarily evaluate a physician's service on a "cure—no-cur basis. That this is true is evident from the type of comment ma by the patient who is cured and the one who is not. If cu results, at worst the patient tends to compare the cost with wh "Dr. X charged Aunt Elsie for the same thing." Cure is uppe most in this patient's mind, with control the intuitive alternati if complete cure is demonstrated as impossible, and the physici is "in for an argument" only when his total fee for that resu is out of line with what the patient thinks is a proper charg (And if the fee—an inclusive one—is presented and accepte in advance of therapy, the patient is unlikely subsequently to consider it improper.) But if therapy is unsuccessful, the patient —especially if the limitations of therapy were not clearly presented and understood—is likely to demand a detailed accounting of all the (futile) services and thereafter to answer any collection efforts with such a rejoinder as "When your fee of $50.00 was quoted to me it seemed like a lot, but I hoped it would be worth it. However, I was really surprised when you ran the bill up to $70.00 and can't see where anything of lasting value was done." Or a son or daughter may protest: "I feel my mother was overcharged for the services she received. The first call was $35.00 and every call thereafter was $5.00, which I don't think was too necessary for what she got out of it. It was just a matter of weighing her once a week." In other words, with fee too closely tied to individual services, the tendency to be analytical and critical predominates. When fee is related, through emphasis on time actually required (even on average) to achieve cure or control, even if the conscientious efforts fail, the patient will be appreciative of the physician's intentions—his total service.

HOW MUCH INCOME

Only the physician himself will be able to determine what amount of income, in the sense of "take-home pay," will satisfy him. The annual figure he decides upon should be one that will enable him to maintain a standard of living acceptable to his own needs and family requirements; to provide for insurance, investment, retirement, and emergencies; and to allow of reasonable luxuries and indulgences. In arriving at this figure, we generally recommend that even the relative beginner select, if tentatively, his eventual goal, since it appears easier to establish a proper fee schedule for the anticipated future than to start "low" with the intention, seldom acted upon, of gradually increasing it later. We recognize that the beginner, and even the man who has been some time in practice, will not achieve his ultimate income as soon as he sets out to rationalize his basic charges, but the foundations will be laid, and he will approach it as rapidly as he brings his practice under control and his productive time becomes filled. Of course the "ultimate" schedule initially chosen must be subject to periodic adjustment, either because a subsequent check of average service/time relations reveals the need for changes, or because the original income decided upon may not prove adequate as the physician grows older, but the former is a matter of adjustment in particular categories and the latter can be effected by a proportionate increase of all fees. Conversely, in times of economic recession, when the physician's dollar income must also decline, this cut is best effected, as it can be, by a corresponding proportionate decrease in fees. Once the physician has settled upon his proper take-home pay, it is an easy matter to determine his income tax obligations, and by adding this tax figure, the net income that he will have to derive from the practice and other sources is readily arrived at. To this he must then add the actual annual expenses (overhead) of the practice to determine the gross income that will have to be achieved.

HOW MANY PRODUCTIVE HOURS

If a physician plans to take off 4 weeks a year for vacations and conventions, and to work six 6-hour days the other 48 weeks, he should, in the course of a year, put in approximately 1,725 productive hours. Supposing the net income goal (before income tax) that he has selected is $1,500 a month and his overhead (a reasonable ratio) is $1,000 a month. He should now gross $2,500 per month, or $30,000 per year. Divided by 1,725 hours, this results in a rate per hour of slightly under $17.50. On this basis a "15-minute office visit" would have to be charged at around $4.50. Most general practitioners, obstetricians, pediatricians, and internists of our acquaintance react to these statements with the rebuttal that they work at least 12 hours per day, charge about that much per office call, yet gross no more than the $2,500 per month we have cited above for the "six-hour per-day" practitioner. One of the major causes of this disparity is the fact, which we frequently can demonstrate to the physician's embarrassment, that he usually spends less than half his total 12 hours productively, that is, in the direct handling of patients. In addition, he generally collects no more than 80 to 85% of his total charges, the 15 to 20% balance of which eventually are sacrificed as uncollectable. (We have assumed, in our $30,000 gross figure above, 100% collections; in practice we find that this should be discounted to 95 to 98% collections in a properly supervised office.) For those several reasons we recommend that the physician be quite conservative in assuming the number of productive hours he will work in the course of a year, so that the hourly rate he applies will tend to produce more rather than less than the desired income.

These same groups of physicians also most vigorously protest that the demands of their practices will not permit them to limit the number of hours they will work. While it is true that a practice controlled by the hourly-rate fee schedule and other concurrent measures can usually be intelligently controlled in respect of hours worked, suppose that a particular physician finds that he must put in more hours than he has planned to. His hourly rate should still be based on the number of hours he desires to work, and if he spends more time (thereby giving up periods of relaxation or time he should devote to his family) he should receive in compensation an income higher than that which he has intended. This increased income may be poor consolation for his being overworked, but it is overtime pay to which he is clearly entitled.

HOW TO CATALOGUE SERVICES

We have presented above, as the third and fourth of the questions asked as essential to determine the basis of fees, what services are performed and how much time each requires in the practice of the individual physician. We have also emphasized, herein and previously,[3] that we believe services should be considered in terms of total care rather than as individual items. The surgeon and obstetrician have successfully applied this principle for many years; its application to medical, as distinguished from surgical specialties, is somewhat more difficult, but many of our clients have confirmed our argument with resounding success. An internist, for example, cannot in good conscience claim that he has insufficient evidence to estimate how many visits his new diabetic patient should require during the first six months of the initial regimen; if he has seen more than a half-dozen diabetics in a private practice of longer than two years' duration, he has in his files data for at least an initial average. With or without this average, he should be able to outline, from his previous training and experience, the "ideal" control regimen he would like to apply to his own diabetic patients. Perhaps the diabetic-control equation is too easy to determine, from the standpoint of total visits and total time involved over a given number of months, but this is no excuse for lazy alibis regarding other specialties or syndromes. We have counselled with general practitioners in working out average fees for such anomalous entities as the common cold, with rheumatologists in treating the protean complexities of the arthritides, and with psychiatrists in setting up extremely complicated therapy programs.

Our major word of caution in establishing the physician's own catalogue of services is that he consolidate it so far as is possible, following his principle of functional definition. (His goal of clarification and simplification is hardly served if he designates over 100 separate types of service in a study of less than 1,000 consecutive patient visits, as we recently observed in one general practice.) At the same time, his desire to "streamline" must not lead him into the equally fatal error of lumping a majority of services performed in the office as "office visits," whether the service was a renewal of dressings by the nurse, requiring none of his time, or if at the other extreme, he spent an hour in exploring and counselling on the patient's interpersonal maladjustments.

FIGURING THE HOURLY-RATE FEE SCHEDULE

Let us assume that we now have the two basic figures to determine desired net income and the set of service/time averages for the practice, so that we may calculate the physician's hourly-rate fee schedule. The simple procedure is then as follows. Divide the determined annual gross income by the number of hours that are to be worked productively in the course of a year. This gives the hourly rate. Multiply the average time arrived at for each service by this hourly rate. This produces the projected (hourly-rate) fee schedule. We have often found it advisable to suggest an alternate method of arriving at final fees for certain specialties, notably surgery and obstetrics, where there will inevitably be productive peaks and valleys. Therefore it is not feasible to base calculations as above, on working such a regular schedule as six hours a day, six days a week, 48 weeks a year. Therefore the hourly-rate fee schedule must be arrived at via a slightly different method of computation. The method of determining the basic hourly rate is identical, the difference lying in the handling of the averaged service/time factor.

When the average time has been arrived at (and, of course, in obstetrics, surgery, and similar specialties, this average time must include all time that is covered by the fee spent preoperatively and postoperatively with the patient), it will then be assigned a point value. For example, 8 hours—8 points and 10¼ hours—10¼ points. Next the physician will estimate how many times in the course of a full year he can expect to render each of the listed services. The number of performances of each service multiplied by the number of points assigned will give the total points for that service. Addition of all totals for individual services will give the grand total of points to be divided into the intended annual gross. The result of this division will be the value of one point. This point value multiplied by the point value of each particular service will give the hourly-rate fee for that service. For example, let us consider a surgeon who only renders five services, as shown in table 1.

TABLE 1.—*Point-Value Equivalent of Total Annual Hours*

Surgical Procedure	Time, Hr.	Point Value	Times Performed Annually	Total Points
1	8	8	20	160
2	6½	6½	28	182
3	10¼	10¼	16	164
4	4	4	34	136
5	15	15	18	270
Grand Total				912

Supposing the intended gross income (as in our previous example) is to be $30,000. The value of a point will thus be approximately $33. The projected fee schedule for this surgeon, with fees stated in round numbers (actual calculated fee in parenthesis) and the results incomewise are given in table 2.

TABLE 2.—*Projected Fee Schedule and Income Results*

Surgical Procedure	Projected Fee	Times Performed Annually	Gross Income
1	$265 (264)	20	$ 5,300
2	$200 (206)	28	5,600
3	$340 (338)	16	5,400
4	$130 (132)	34	4,420
5	$500 (495)	18	9,000
			$29,720

Fee Adjustments.—Whichever method of fee computation is applied, when the projected fee schedule is arrived at, it will be found that, while the majority of the fees will not vary markedly from those already in effect, there will be a few in which conversion to the projected hourly-rate fee schedule will mean a radical revision either upwards or downwards. While we do not deviate from our basic premise that each physician is entitled to establish fees proper to his personal approach and activity and should do so, we cannot practically propose immediate alterations so marked that they draw unfavorable attention to the changes, and in these instances we counsel progressive modifications toward the desired level.

The reason why there will be such occasional differences is the arbitrary manner in which existing fee schedules are customarily developed. For example, a surgeon may today charge $200 for a procedure that involves no more than 4 hours, and only $400 for one that involves 15 hours (frequently because these are the "going rates" established or accepted by insurance companies), whereas we have seen, in the examples cited, that these fees should be $130 and $500 respectively. As an interim step, in such a situation, we would probably propose the reduction of the $200 fee to $175 and an increase in the $400 to $450. (It will be noted that, in our example, this would make little or no difference incomewise.) Later, as the physician's education of patients becomes more effective, it may be possible to bring these fees more closely into proper relationship.

Recently we were asked why the revision of a fee schedule to conform to those published by insurance companies would not provide a "fair" schedule, since the insurance fees were "actuarially based." We pointed out that, while the insurance company actuarially arrived at the premiums that would have to be charged by relating fees to incidence, the approved fees were more likely to reflect an average of prevailing fees already being charged across the country than fees that they had themselves selected by relating service to time. These "prevailing fees," which form the basis of insurance schedules, have thus evolved by the same arbitrary method producing the discrepancies to which we have previously referred. We must all recognize that, theoretically sound and certain as the hourly-rate basis is, it cannot work out perfectly in practice because we are dealing with unpredictable factors both in the physician and the patient. The intended gross income will be the ideal that the physician strives for and reasonably approaches. Its effective attainment will be limited by allowances he makes to truly deserving patients, professional courtesy discounts, and, on the reverse side of the ledger, "contingency fees," which he adds to his basic fee, despite the fact that average time already has made some allowance for the abuses that call for them. Such fees are proportionally charged to patients who, for one reason or another, make unusual and unreasonable demands on the physician's time. (Allowances, professional courtesy, and contingency fees will be discussed in the next article in this series.) Other modifying influences are the rounding-off of fees, which in the surgical example produced a deficit of $280 below the intended gross income, and also the fact that performance cannot be expected to work out exactly as it is projected.

The physician's intended income calculations should therefore be protected on the upward side. Part of this protection will come, as we have already seen, from the fact that he will likely be forced by the demands of emergency services to work longer hours than he desires. A second means of securing his position is by the device of ignoring in his basic calculations separately charged office visits, except when they are the mainstay of the practice and cannot be reduced. There should be a charge for all such office visits as cannot be covered by an inclusive fee, and this charge will be based on the hourly rate, but the hourly rate will be arrived at by excluding office visits (especially where the point system approach is used) from the calculations. Thus the income derived from office visits will be an override that will compensate for unavoidable leaks in other areas. (When the "productive hours" basis is used, office visits are excluded by proportionally reducing the daily number of productive hours.) Finally, the hourly-rate fee schedule arrived at must never be regarded as immutable. Periodically, on the basis of additional experience, the physician should refigure his "average time per service," and if there is marked variation from the figures used in the original calculations, the particular fee should be recalculated and the fee adjusted accordingly.

ADVANTAGES OF THE HOURLY-RATE BASIS

While we have conceded that there may have to be some deviation from the ideal and accurately calculated fees set for the above, the greatest advantage of the hourly-rate basis is the sense of security that it gives the physician and his staff in presenting fees to patients. They know that the fee presented has been fairly determined and is therefore fair both to the physician and his patient. The lack of assurance with which most physicians present their fees today, and the fact that from time to time (and usually for the wrong patients) they vary the fee schedule established in their offices on an arbitrary basis, springs in large measure from their subconscious doubts of the validity of the fees they are presenting and of the basis on which their fee schedule was initially developed. When a physician knows that the fee he is presenting is proper to the service he is rendering, he knows also that he merely has to present it—that he does not have at the same time to justify a figure that he is not sure he can rationally justify. In other words, he can present it with full assurance as to its propriety. If there then develops any valid reason for departing from his established schedule, he can do so on a sensible and rational basis, knowing exactly what he is doing and also what effect it will have on his own earnings.

1955 Franklin St., San Francisco (9) (Mr. Porterfield).

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Malpractice: Liability of Industry for Negligence of Company Physician.—The plaintiff sued the Scullin Steel Company, his former employer, for damages for injuries allegedly caused by the negligence of its employees, particularly its company physician. From a judgment for the defendant, the plaintiff appealed to the Supreme Court of Missouri.

When the plaintiff entered the defendant's employment in February, 1943, the company physician, Dr. Leo Will, gave him a physical examination that showed that the plaintiff was in good physical condition except for a heart lesion. An x-ray revealed a slight enlargement of the heart, caused by the constant pulling up of the muscle. Dr. Will told the plaintiff that he heard a murmur in his heart, but he approved him for manual labor. Except for several short periods of time, the plaintiff served as an employee of the defendant company until February, 1949. During this time, the plaintiff worked in the core room and handled cores weighing from 25 to 175 lb. In July, 1948, he fell against a core stand and experienced a pain in his chest or heart. He saw Dr. Will about the condition, but Dr. Will merely examined him, had an x-ray taken, prescribed medicine, and advised him to take things easy. Later that year the plaintiff was examined and treated at a medical center and learned for the first time that he had been suffering from cardiovascular syphilis. In February of 1949, the plaintiff was told by Dr. Will to go home and to obtain the care of a private physician. In March he became the patient of a Dr. Melvin Goldman, who treated him through 1951 for syphilis. An electrocardiogram taken in March, 1949, showed the condition of the plaintiff to be normal; one taken in June, 1950, showed some enlargement of the left ventricle; and one taken in September, 1951, showed some moist rales, indicating moisture in the lung. A complete examination on Sept. 14, 1951, also showed a questionable edema of the ankle. All x-rays taken by Dr. Goldman showed essentially the same condition as those taken by Dr Will.

The theory of the plaintiff's suit was that the defendant, through its employees, had ordered him to do work that he was not physically capable of doing; that the defendant knew or had reason to know of his disability; and that the doing of manual labor for the defendant had aggravated his heart condition and shortened his life expectancy. Dr. Will described the heart condition that he discovered before the plaintiff commenced to work for the defendant as a "sea gull" murmur. He stated that he had never heard such a murmur before and that he could not tell which heart valve was involved but that at no time during the plaintiff's employment did he find signs of decompensation. Dr. Will explained that he approved prospective employees for manual labor, even though they had heart murmurs, unless there were signs of decompensation, because in his opinion a person with a heart murmur would not increase decompensation any more by manual labor than he would by remaining inactive. Furthermore, the plaintiff never complained of trouble with his heart until after the accident in 1948, and the examination given at that time still did not show signs of decompensation. Until the time of the trial Dr. Will was unaware that the plaintiff had syphilis. Dr. Goldman, testifying for the plaintiff, substantiated Dr. Will's testimony of the plaintiff's condition while employed by the defendant and disclosed that the accident contributed to and aggravated his heart condition, precipitating decompensation and possibly thrombosis.

The Supreme Court first pointed out that the instant case is not like the situation where an employer has been warned that his employee has a disability and can not do certain types of work but nevertheless orders the employee to do the forbidden work. Rather, the instant case presents a question of whether the company physician acted negligently in deciding that the plaintiff could do manual labor without it resulting in physical harm to the plaintiff. The defendant could not be liable unless the physician himself was liable. There was no question, said the court, as to Dr. Will having the requisite skill and knowledge to perform the tasks required of him as the company physician. The court further pointed out that no witness, expert or otherwise, testified about Dr. Will not acting according to the accepted standards of practice in that community in either examining the plaintiff or recommending him for manual labor. Dr. Goldman merely testified that in his opinion he would not have so recommended the plaintiff. The Supreme Court held that, on the basis of such testimony, one could merely conclude that Dr. Will had a medical opinion that differed from that of Dr. Goldman. A difference of medical opinions does not indicate that one of the physicians acted negligently, however. Accordingly the court affirmed the judgment in favor of the defendant company. *Brown v. Scullin Steel Co., 260 S. W. (2d) 513 (Mo., 1953).*

Childbirth: Liability for Prenatal Injuries.—The plaintiff, a minor, sued for prenatal injuries caused by the defendant's alleged negligence. From an order of the trial court, the defendant appealed to the supreme court, appellate division, third division, New York. Prior to his birth, and when his mother was in the third month of her pregnancy, the plaintiff was injured when the defendant struck and knocked down his mother while driving an automobile. As a consequence the plaintiff was born weakened, debilitated, and otherwise physically handicapped. The defendant maintained that a person could not recover for prenatal injuries that were inflicted before such person had reached the stage of viability.

In 1951 the Court of Appeals held that a person could recover for prenatal injuries inflicted during the ninth month of the mother's pregnancy. That case dealt with injuries to an unborn but viable child, and the appellate division held that the same rule should apply even though the unborn child was injured prior to the ninth month. In determining when a person becomes capable of acquiring legal rights, the time of conception, said the court, was more important than the time of viability. At the moment of conception the fetus becomes an entity distinct from the mother and may be physically separated as a distinct entity, and the fact that a nonviable child would not survive if separated should not be used as a basis for denying the child certain rights that normally accrue to every individual person. In conclusion, the court held that if the child, born after an injury sustained at any period of his prenatal life, can prove the effect on him of the tort, he makes out a right to recover. Hence, the supreme court affirmed the decision of the lower court for the plaintiff-infant. *Kelly v. Gregory, 125 N. Y. S. (2d) 696 (N. Y., 1953).*

Workmen's Compensation Acts: Injury Without Loss of Earning Power; Compensability.—In a claim for an award under the Workmen's Compensation Act, the industrial commission found in favor of the employer. The claimant then appealed to the Supreme Court of Oklahoma. While working at a mine owned by his employer, the claimant inhaled fumes from a chemical preparation containing xanthate, which was used in processing materials at the mine. The inhalation caused the claimant to lose his sense of smell and partially his sense of taste. An award was denied on the grounds that the claimant had suffered neither an accidental injury nor any loss of wage-earning capacity.

The Supreme Court held that the inhalation of fumes by an employee while acting within the scope of his employment constitutes an accidental injury within the meaning of the workmen's compensation law. It also held that it was immaterial to the right to recover that the claimant suffered no loss of earning capacity. The compensation law, said the Supreme Court, provides for a set rate of compensation to be paid for permanent disabilities, even though they do not effect a loss of the employee's earning capacity. Accordingly, the Court reversed the denial of compensation and remanded the case for further proceedings. *Ford v. Nellie B. Mining Co., 255 P. (2d) 504 (Okla., 1953).*

INTERNAL MEDICINE

Successful Short-Term Therapy of Streptococcal Endocarditis with Penicillin and Streptomycin. B. Hall, H. F. Dowling and W. Kellow. Am. J. M. Sc. **230:**73-81 (July) 1955 [Philadelphia].

During the past three years Hall and associates treated 15 patients with endocarditis caused by penicillin-sensitive alpha and gamma Streptococcus organisms with short-term penicillin and streptomycin therapy. In each case the diagnosis was established by 2 to 11 (average, 5) positive blood cultures. In 10 cases, an alpha Streptococcus was isolated, while a gamma Streptococcus was found in the remaining five. In all except two of the patients the organisms were sensitive to 0.1 unit of penicillin or less per cubic centimeter. In 11 of the 15 cases streptomycin sensitivity of the causative organism was determined, and it ranged from 0.2 to 50 mcg. per cubic centimeter. In 11 patients the underlying heart disease was of rheumatic origin. In three patients, diagnoses were calcific aortic stenosis, syphilitic aortic insufficiency, and tetralogy of Fallot, respectively. One patient may have had a normal heart prior to the onset of bacterial endocarditis. Antibiotic treatment was started as soon as the results of blood cultures became known. In some instances, digitalis, mercurial diuretics, and blood transfusions were also employed. The usual plan of antibiotic treatment consisted of the intramuscular injection of 600,000 units of aqueous procaine penicillin G at six hour intervals for 10 days, for a total dose of 24 million units. Streptomycin, or, more commonly, a mixture of equal parts of streptomycin and dihydrostreptomycin, was given concurrently in a dose of 0.5 gm. at 6 hour intervals for 5 days, and 0.5 gm. at 12 hour intervals for another 5 days, for a total of 15 gm. in 10 days. In a few of the patients treatment was continued for 13 or 17 days. Two of the patients died while hospitalized for treatment, and a third patient continued to be febrile and was successfully re-treated with larger doses of penicillin alone for six weeks. The 12 remaining patients were successfully treated by short-term combined antibiotic therapy. The authors show that the short-term therapy is the more desirable, since a regimen of four to six weeks of therapy, such as has been found necessary in the past, has many disadvantages.

Myocardial Infarction in Younger Age Groups. L. V. McVay Jr. J. M. A. Alabama **25:**1-8 (July) 1955 [Montgomery, Ala.].

Age is generally regarded as an important factor in myocardial infarction, but those who have witnessed many autopsies are aware that coronary atherosclerosis may occur in relatively young persons. This was strikingly illustrated by Enos, who demonstrated that 77% of American soldiers killed in Korea had coronary atheromas. This report is concerned with 34 patients with myocardial infarction, who were observed at the Maxwell Air Force Base Hospital, during a four year study. There were 17 aged 40 or less, and 17 were 41 or over. That not a single coronary occlusion occurred in a Negro patient is regarded as indicative of a racial factor. Other factors that seemed to play a part in the pathogenesis of coronary occlusion were: a familial history, obesity, excessive use of tobacco and alcohol, as well as unusually strenuous activity. In Alab myocardial infarction seems to occur more commonly du the warm season. Myocardial infarction is often overlooke young persons, chiefly because it is regarded as uncommon because the clinical picture may be atypical. Serial electrocar grams, sedimentation rates, and white blood cell counts frequently required to establish the diagnosis definitely. laboratory procedures, however, can substitute for clin observation and alertness.

Anticoagulant Treatment in Myocardial Infarction. J. He mann. Harefuah **48:**190-192 (May 1) 1955 (In Hebrew, Eng Abstract) [Jerusalem-Tel Aviv, Israel].

On the basis of observations in the treatment of 231 pati with myocardial infarction, the author advises the use of bi droxycoumarin (Dicumarol), since it prevents one of the important and often fatal complications. The mortality in of the cases treated with bishydroxycoumarin was 9%, exclu patients who died during the first three days after admiss In only two of the patients treated with bishydroxycoum did thromboembolic complications occur. They appeare one patient three days and in the other 10 days after stop treatment with bishydroxycoumarin. Of the 51 patients treated with anticoagulants, 18% experienced thromboem complications. The author thinks that the use of anticoagul in patients with myocardial infarction was partially respon for the low mortality rate observed and not only thr prevention of thromboembolic complications. Bishydroxy marin should be continued despite fluctuations in the proth bin time, which may occur during treatment, because thron embolic complications did not occur more often in cases great fluctuations in the prothrombin time. Only a small nun of other complications occurred in patients with myocardia farction in the course of the treatment with bishydroxycoum

Osler's Endocarditis Lenta Due to Streptococcus Resistan Other Antibiotics, Cured by Erythromycin. J. Lambert Lamalle and R. Lievens. Acta clin. belg. **10:**62-68 (Jan.- 1955 (In French) [Brussels, Belgium].

A case of subacute bacterial endocarditis (endocarditis le is reported. The patient's blood culture was consistently neg for a month, after which period nonhemolytic streptococci isolated that were resistant to penicillin, streptomycin, ox racycline, and chloramphenicol; slightly sensitive to chlo racycline; and definitely sensitive to erythromycin. Treatn with combined penicillin and streptomycin in massive d and then with oxytetracycline given intravenously, both before the hemogram became positive, was a complete ure. Clinical cure was obtained by the administration erythromycin alone; the dosage was 2 gm. a day for a m with progressively decreasing doses during a second mo No side-effects were observed. There has been no recurr in a follow-up period of five months. Thus it is seen that eryt mycin alone can be effective in the treatment of suba bacterial endocarditis of Osler. This knowledge gains gre value in the light of the growing resistance of the patho to various antibiotics.

Results with a Combination of Rauwolfia and Adrene Blockade in the Treatment of Hypertension. J. H. Mo W. Hughes, E. Dennis and others. Am. J. M. Sc. 230:3 (July) 1955 [Philadelphia].

Hypotensive effects of Rauwolfia plus phenoxybenza (Dibenzyline), and of these two drugs in combination protoveratrine were compared in 47 patients with var degrees of hypertension. A significant hypotensive respons mean blood pressure reduction of 20 mm. Hg or more,

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

achieved in 23 of 28 patients receiving the combination of Rauwolfia, protoveratrine, and phenoxybenzamine. Of 19 patients receiving only Rauwolfia plus phenoxybenzamine, 14 experienced significant blood pressure response, but this latter group of patients had slightly more severe hypertension, in that all had previously been unresponsive to Rauwolfia alone. Side-effects of all regimens (including Rauwolfia alone) were seen in nearly all patients. Chief side-effects of the Rauwolfia-protoveratrine - phenoxybenzamine combination consisted of nasal congestion, sedation and fatigue, increased appetite, dizziness, and bradycardia. Orthostatic tachycardia, a major side-effect of phenoxybenzamine alone, was seen infrequently when the drug was used in this combination. The dose requirement of phenoxybenzamine was greatly reduced as compared with that required when this agent was used alone. Results indicate that the combination of phenoxybenzamine and Rauwolfia, with or without protoveratrine, may prove generally useful in the treatment of all degrees of hypertension. Rauwolfia blocks vasoconstrictor impulses centrally, whereas phenoxybenzamine blocks vasoconstrictor impulses peripherally; together these effects make this a potent combination for reducing the blood pressure in patients with hypertension.

Malignant Hypertension: Clinical Study. M. Plaza de los Reyes, R. Gómez and L. Szpirman. Rev. méd. Chile 83:234-240 (April) 1955 (In Spanish) [Santiago, Chile].

In the Hospital Clínico of Santiago, Chile, 26 patients with malignant hypertension were observed. There were 8 female patients and 18 male. Most of the patients were between the ages of 20 and 50 years. All of the patients were in a poor general state of health with high arterial hypertension, a diastolic pressure above 130 mm. Hg, hypertensive encephalopathy, and retinopathy. Arterial hypertension had lasted for more than two years in 15 patients. The disease proved to be of nephrogenic origin in half the patients and either essential or of unknown origin in the remaining. Chronic pyelonephritis was the cause in seven women and in three men, and chronic glomerulonephritis in three men. The symptoms of hypertensive encephalopathy were headache in all patients and a great diminution of vision in 11 patients. Other disorders of vision and hearing, and vomiting and insomnia were observed in the remaining patients. The average systolic-diastolic pressures for the group were 239/153 mm. Hg respectively. A diastolic pressure of 150 mm. Hg or more was observed in 19 patients in whom the renal plasma flow was greatly diminished. A histopathological study of the kidney was made in six cases by biopsy during an operation and in four cases after autopsy. The lesions were those of malignant nephrosclerosis in four cases, nephrosclerosis and chronic pyelonephritis in four, and chronic extensive glomerulonephritis and benign nephrosclerosis in a case each. The authors conclude that malignant hypertension develops in two stages. In the early stage hypertension increases as a result of functional renal disorders that can be controlled by medical or surgical treatment, causing hypertension to reverse to normal or nearly normal figures. The second stage consists of progressive increase of diastolic hypertension that produces acute arteriolar lesions of malignant nephrosclerosis, cerebral edema, and hypertensive encephalopathy. The disease can be either primary and of rapid course and poor prognosis or secondary to nephrogenic hypertension.

Brill-Symmers Disease with Splenohepatorectal Localization. B. Wissmer, H. Dubois-Ferrière, E. Naz and P. Wettstein. Arch. mal. app. digest. 44:273-290 (March) 1955 (In French) [Paris, France].

A case of giant follicular lymphoma (Brill-Symmers disease) with unusual localization limited to the spleen, liver, and rectum was seen in a 56-year-old woman. When first seen by the authors, she was suffering from severe bloody diarrhea, had ascites, was cachectic, and had been given a rapidly fatal prognosis. The true nature of her disease was not discovered until the spleen was examined microscopically after splenectomy, although she had undergone a battery of clinical and laboratory tests. The combination of splenectomy and roentgen irradiation of the liver and rectum restored the patient to excellent health. This case is a good illustration of the confusion arising when giant follicular lymphoma remains undiagnosed because it is not envisaged as a possibility. The diagnosis was especially difficult here because there was no adenopathy. Malignant giant follicular lymphoma is a fairly rare disease; there are about 200 cases of it reported in the literature. It occurs most commonly in persons between 40 and 60 years of age. Its characteristic symptoms are generalized adenopathy and splenic involvement with splenomegaly. There are no general signs of the disease, and the blood picture is normal. Some forms can be localized to a single organ. The disease evolves slowly toward generalization and sarcomatous transformation; occasionally lymphocytic leukemia or Hodgkin's disease is the end-result. The increase in size and number of the lymphatic follicles can be seen macroscopically. The diagnosis can be made from histological data only. Clinical differential diagnosis must be made from lymphoid leukosis, Hodgkin's disease, chronic inflammatory adenitis, Banti's disease, and lymphosarcoma, among others. Since the disease is highly radiosensitive, remissions can be induced that may last five years or longer. Actinomycin also appears to be of value in this therapy.

Sarcoidosis: Uveoparotid Fever. V. Contreras Vilu and R. Valdivieso D. Rev. méd. Chile 83:250-252 (April) 1955 (In Spanish) [Santiago, Chile].

The subject of this report, a man 38 years old, was normal up to the appearance of the typical symptoms of uveoparotid fever, including unilateral facial paralysis and great damage to the eyes. During the first attack the treatment consisted of sulfadiazine given orally up to a total dose of 17 gm. and local application of cortisone solution. Two recurrences followed at intervals of one year. During the second recurrence a large tumor developed in the right parotid gland that was removed under the diagnosis of a mixed parotid tumor. Histological study showed it to be tuberculous lymphadenitis. One year later a large tumor developed in the left parotid gland. Biopsy showed tuberculosis. Examination for bacilli and the tuberculin tests were negative. Roentgen examination of the chest showed bilateral chronic pneumonia of the interstitial type. The tests for sarcoidosis were positive. A review of the histological preparations changed the diagnosis from tuberculosis to sarcoidosis. The treatment consisted of cortisone administered in a dose of 150 mg. and maintenance doses of 50 mg. each, to a total dose of 3 gm. The general condition of the patient improved, and the size of the left parotid gland greatly regressed. The roentgen aspect of the lung and the ocular lesions did not change. Loss of vision was almost complete when the patient was discharged. The authors direct attention to the importance of early treatment with corticotropin and cortisone. These drugs prevent the progress of early ocular lesions, cause improvement in the general state of health, and stimulate spontaneous remission of the disease. The results are transient.

Medical and Social Aspects of the Treatment of Rheumatoid Arthritis with Special Reference to Factors Affecting Prognosis. J. J. R. Duthie, M. Thompson, M. M. Weir and W. B. Fletcher. Ann. Rheumat. Dis. 14:133-149 (June) 1955 [London, England].

The objectives of the reported studies were to assess the immediate results of treatment in hospital on patients with rheumatoid arthritis; to ascertain how long improvement could be maintained after discharge; to determine the relationship between clinical progress and changes in social and economic status; and to obtain information about factors that might help to predict the response to treatment of individual patients. The original group consisted of 307 patients admitted to hospital between June, 1948, and July, 1951. Of this group 282 were available for assessment at the last follow-up examination. It was found that the admission to hospital of patients with rheumatoid arthritis is followed in the majority of cases by a substantial improvement in functional capacity and a significant decrease in the activity of the disease. Improvement is well maintained after discharge, although a more prolonged follow-up is required before it can be claimed that the natural course of the disease has been significantly altered. A close relationship exists between improvement in the medical sense and betterment of social and economic circumstances. When advice and help are available, increase in functional capacity leads to increased efficiency at home and at work. In predicting the immediate response to treatment and the subsequent course of the disease, the most important single factor appears to be the duration of symptoms before admission to hospital. Patients admitted within one year of onset respond very satisfactorily to the basic regime of treatment, and the majority continue to improve after discharge. However, results at this stage of the disease may be favorably influenced by the admission of a proportion of patients in whom the disease is destined to run a relatively benign course. An acute onset followed by a rapidly progressive course in the early stages may indicate a rather benign form of the disease. The erythrocyte sedimentation rate and the disease activity on admission have little bearing on prognosis. Mild or moderate anemia on admission is not of grave significance, but, when anemia is severe, response to treatment is less satisfactory. Social and medical supervision may play a part in consolidating the benefits of hospital treatment. The medical social worker occupies a key position in the organization of long-term care and follow-up. The results that follow the conservative forms of treatment in hospital compare favorably with those claimed for other forms of treatment, such as the administration of gold or cortisone.

Undiagnosed Lung Diseases: A Survey of One Hundred Consecutive Supraclavicular Biopsies. E. F. Skinner and J. R. Hall. Memphis M. J. 30:78-80 (July) 1955 [Memphis, Tenn.].

Skinner and Hall resorted to supraclavicular biopsy in 100 patients in whom pulmonary diseases could not be diagnosed with the usual diagnostic procedures, such as skin tests for tuberculosis and histoplasmosis, bronchoscopy and bronchial washings, bronchograms, multiple sputum studies for tubercle bacilli and tumor cells and fungi, pleural fluid studies when pleural fluid was present, bone marrow examinations, fluoroscopy, x-rays of the chest in various projections, and even in a few cases lung biopsy or biopsy of the chest wall and axillary nodes. The surgical approach to supraclavicular biopsy was essentially the same as that used in a phrenic nerve operation. The fat pad lying on the scalenus anterior muscle is removed, together with its contained lymph nodes. By pulling on this fat pad, lymph nodes can be removed from beneath the clavicle and from the superior mediastinum. A supraclavicular node biopsy is essentially a superior mediastinal lymph node biopsy. All of the right lung and the left lower lobe and a portion of the left upper lobe usually drain into the right supraclavicular nodes, and the left supraclavicular nodes drain chiefly the left upper lobe, excluding part of the lingula. This information is useful in deciding on which side to do the supraclavicular node biopsy. Positive biopsy reports were obtained in 43 and negative ones in 41 of the 100 patients. The remaining 16 patients also had negative biopsies, but in these a positive result could not be expected, since they had medical diseases such as bronchiectasis, pneumonia, and so on. No fatality resulted in the 100 supraclavicular biopsies, and there was little morbidity. Hospitalization usually averaged 48 hours. In many of the cancer patients a positive supraclavicular biopsy saved the patient from major surgery, as such distant metastases made surgical cure highly improbable. Supraclavicular biopsy should be performed irrespective of whether or not nodes are palpable in the neck. There were 18 among the 100 patients in whom no nodes were palpable and yet the supraclavicular biopsy yielded a positive report. In addition to pathological examination the resected nodes should also be studied bacteriologically for tubercle bacilli and fungi.

Prognosis of Infantile Tuberculosis. P. Fornara. Minerva med. 46:1027-1039 (April 12) 1955 (In Italian) [Turin, Italy].

The prognosis of infantile tuberculosis, which was almost always fatal in the preantibiotic era, has been revolutionized by the discovery of antibiotics. With chemotherapy and antibiotic therapy, primary tuberculosis can today have a favorable course. This was proved by a comparative study of two episodes of contagion that were observed in the preantibiotic and antibiotic eras respectively. The first occurred in a Novara Foundling Hospital in 1928, and the death rate was 73.82%; the second occurred in a kindergarten in the province of Milan in 1951, and the death rate was 3.7%. Generally, if a child is still alive one month after his removal from the source of contagion, his survival tends to become definitive; if he does not die within one and one-half years after the first signs of the infection, it is almost certain that he will not die of primary tuberculosis. All children with a primary infection should be watched carefully and made to follow special precautions, especially during the first 4 to 5 months, and for at least 18 months from the onset of the condition. Chemotherapy combined with antibiotic therapy gives good results. Infants under 6 months of age should be given streptomycin, *p*-aminosalicylic acid, and isoniazid; older children should be given isoniazid and *p*-aminosalicylic acid. With these therapies, forms that in the preantibiotic era would have progressed toward caseation and massive cavitation are arrested and healed. Prognosis of the local complications of primary tuberculosis depends on the time in which therapy is started and on the patient's degree of resistance. If this i satisfactory, primary tuberculosis and its local complication are cured, otherwise the tuberculous lesions tend to develop into a progressive type of pulmonary tuberculosis. The prognosi of tuberculous meningitis and miliary tuberculosis, which wa fatal in all cases, has also been favorably influenced by th discovery of antibiotics, and especially of streptomycin. Th author has obtained good results in tuberculous meningitis with streptomycin given intrathecally and intramuscularly combined with isoniazid given intramuscularly and orally and *p*-amino salicylic acid given orally. He rejects treatment of tuberculou meningitis with isoniazid alone. He reports good results i patients with miliary tuberculosis to whom he administere streptomycin at first combined with sulfone, then with *p*-amino salicylic acid and thiosemicarbazone, and later with isoniazid

Prognosis of Hepatic Cirrhosis. M. Coppo. Minerva me 46:989-992 (April 12) 1955 (In Italian) [Turin, Italy].

The prognosis of hepatic cirrhosis is fatal (except for a fe rare cases), the main feature of the condition being atroph of the liver as a specific and functioning tissue. The disease, an therefore its prognosis, has not been substantially modified b modern treatment; this merely slows down the progression of th condition and checks some of its symptoms and their cons quences. Despite present day therapy, 70% of patients wit cirrhosis die within five years of its clinical diagnosis. Th prognosis depends on an exact diagnosis and on the phas reached by the cirrhosis. Ascites is a grave sign, and when is the result of the progressing of the disease the prognosis poor. Jaundice accelerates the progression of the cirrhosi Biopsy, which is a valuable diagnostic means, is of little us for the prognosis because it is limited to one particular are of the liver, whereas the prognosis is based on the conditio of the entire organ and on its regenerative power. The mai point of the prognosis lies within the liver itself, namely, o the cirrhotic-damage/liver-resistance ratio. The fatal prognos of this condition can be modified by (1) prophylactically pro tecting the liver from all injuries, because any hepatic impai ment may become the starting point of the condition; (2) mai taining or stimulating the regenerative powers of the liver an the rebuilding of the impaired parenchyma; and (3) trying t reach an early diagnosis of the cirrhotic damage so that it may b either kept within a restricted area or eliminated in the initi phase, the only time in which this is possible.

Carcinoid in Small Intestine: Cases with Metastases to Live Stenosis of Tricuspid, and Unusual Form of Cyanosis: Ne Syndrome. K. H. Olesen. Ugesk. læger **117**:635-639 (May 19 1955 (In Danish) [Copenhagen, Denmark].

A peculiar triad has received increasing attention durin recent years. In the first of the two cases described all thre components were present: carcinoid in the small intestine wit hepatic metastases, tricuspid stenosis and pulmonary stenosis without septum defects, and unusual cyanosis. In the second case there were two components, carcinoid with hepatic metastases and tricuspid insufficiency. The origin of the cardiac changes in the syndrome is uncertain. An early cutaneous symptom is the paroxysmal light to dark flush, later alternating with dark cyanotic spots or intense brick-red surfaces. The changes as a rule begin in the face and on the throat and extend to the trunk and extremities. The carcinoid is thought to be primary and the cutaneous changes are explained as secondary and due to the vasoactive substance enteramin, or serotonin, produced in the carcinoid, and the tricuspid defects, also secondary, are attributed to the protracted influence of enteramin on the cardiovascular system (Waldenström and co-workers).

Malignant Carcinoid of Small Intestine with Pulmonary Stenosis: Tumor Producing Serotonin? K. D. Carlsen and T. Søndergaard. Ugesk. læger 117:639-641 (May 19) 1955 (In Danish) [Copenhagen, Denmark].

A case is reported of malignant carcinoid of the small intestine with pulmonary stenosis and reddish-blue cyanosis in a man, aged 65. The hypothesis is that the release of large amounts of serotonin, or enteramin, from the carcinoid tumor can lead to vascular changes peripherally and in the pulmonary circulation. If vasoactive serotonin is excreted by the carcinoid tumors, establishment of the substance in the blood and urine should be a valuable diagnostic aid in suspected malignant carcinoid.

SURGERY

Surgery of Hypertension. G. H. Yeager. South. M. J. 48:635-639 (June) 1955 [Birmingham, Ala.].

A group at the author's clinic made an attempt to obtain more information on the value of adrenalectomy in hypertension. The patients studied were selected on the basis of the following criteria: A rapidly progressive hypertensive state, papilledema with hemorrhagic exudates, and the absence of any demonstrable primary etiology for the hypertension. For the purpose of comparison, the patients were divided into three groups. The first contained six patients who died during the initial period of observation, before any therapeutic procedure could be undertaken. The second group contained five patients who were subjected to some form of adrenal surgery and all of these died. The third group contained six patients who were treated by the combined procedure of sympathectomy and total adrenalectomy. Observations on these groups suggested that better control of blood pressure and more satisfactory clinical results could probably be obtained by combining thoracolumbar sympathectomy with adrenalectomy. Better results might possibly have been achieved by rejecting patients with advanced renal disease, and by avoiding bilateral single stage operations. The author was unable to demonstrate reversibility of severe renal disease associated with hypertension. Failure to observe replacement requirements after adrenalectomy in any form of stress may lead to the development of a rapidly fatal adrenal insufficiency, if adequate substitutive treatment is delayed. With the development of more effective drugs in the treatment of hypertension, the surgical management of any phase of this disease is becoming increasingly rare. Potent ganglionic blocking agents give promise of such a degree of effectiveness that it is conceivable that an era is being approached when surgical intervention, even in the late stages of hypertension, will be outmoded.

Surgical Treatment of Constrictive Pericarditis. W. Ying-K'ai, C. T'ien-Huei, H. Kuo-Chun and others. Chinese M. J. 73:122-132 (March-April) 1955 (In English) [Peking, China].

The authors present experiences in 73 pericardiectomies carried out in 70 patients with constrictive pericarditis between 1948 and 1954. The patients ranged in age from 5 to 53 years, and all but 13 were males. Nearly three-fourths were in the second and third decades of life. It is generally accepted that constrictive pericarditis is usually tuberculous. In 35 cases, the resected specimens proved to be tuberculous. It seems very likely that in most of the other cases the tuberculous lesion had healed and only fibrous tissue was left behind as a result of the long duration of the disease. There were 10 postoperative deaths during hospitalization; 39 patients have been followed up for periods ranging from six months to six years; 26 of these 39 were cured, and 5 others were improved. There were six late deaths. An analysis of the fatal and unimproved cases shows that most of these were chronic cases in which there were either marked impairments in cardiac and hepatic functions or technical shortcomings in the operation. Improvements in timing the operation, in the preparation of patients for operation, and in the operative technique will give better results in the surgical treatment of constrictive pericarditis. During the early stage of tuberculous pericarditis, when the chief disturbance of cardiac function is due to pericardial effusion, treatment should consist of conservative measures. Operation is done when pericardial constriction develops. The resection of pericardium should be adequate, including the pericardium over the anterior aspects and the lateral borders of both ventricles. It is not absolutely necessary to resect the pericardium over the auricles. The advantages and disadvantages of the median sternotomy incision and the left parasternal incision are discussed. Treatment with antituberculous drugs is advisable before and after pericardiectomy. Postoperative drug therapy should be continued longer in patients with active tuberculous infection.

Use of Active Vegetable Substances in Preparing Patients with Thyrotoxicosis or with Basedow's Exophthalmic Goiter for Surgery. H. Sittig. München. med. Wchnschr. 97:826-832 (June 24) 1955 (In German) [Munich, Germany].

When it was observed that, despite Plummer's preparatory iodine treatment, severe thyrotoxic crisis often resulted after operations on the thyroid, the author decided to refrain from the preoperative use of iodine. It is difficult to ascertain how individual patients will react to (Lugol's) strong iodine solution, since response may range from refractoriness to hypersensitivity. Instead of strong iodine solution, the author used standardized extracts of Lycopus virginicus. (Lycopus is a genus of nonaromatic mints, known as the bugle-weeds.) Such extracts were used in 91 patients, 80 with moderately severe and 11 with severe thyrotoxicosis, and in 10 patients with Basedow's exophthalmic goiter. All were rendered suitable for surgical treatment. The time required for preliminary treatment increased with the severity of the patient's clinical status, and often was considerably longer than that required for Plummer's iodine therapy. The use of the Lycopus extract had the advantage, however, that the postoperative thyrotoxic crisis was very mild. As regards the technique of the operation, the friability of the thyroid was not increased as it is after preparatory treatment with the thyrostatic drugs. The condition of the thyroid after treatment with Lycopus extract was about the same as after iodine therapy. Furthermore the operation can be postponed longer and is not as definitely determined by the transition point as is the case with Plummer's preparatory iodine treatment. It was noted also that the patients were much more rapidly restored to normal and were able to resume their occupation earlier after operation than was the case in those who received Plummer's iodine preparation.

Resection of Lung for Pulmonary Tuberculosis. H. Chia-Ssu, S. Mei-Hsing, C. Chung-Hsi and W. Teh-Hsing. Chinese M. J. 73:112-121 (March-April) 1955 (In English) [Peking, China].

From 1947 to the end of June, 1954, a total of 313 pulmonary resections were done on 312 patients with pulmonary tuberculosis at the Clinic of Thoracic Surgery of the Shanghai First Medical College. The series included 89 pneumonectomies, 144 unilobar lobectomies, 8 bilobar lobectomies, 20 segmentectomies, 14 wedge resections, 21 multiple resections, and 17 pleuropneumonectomies and pleurolobectomies. The indications for operation were considered as absolute in 231 cases and relative in 82 cases. Tuberculous spread or exacerbation in the remaining lung occurred early or late in the postoperative period in 25 patients. Drainage of bacilli-laden sputum to the contralateral lung seems to be the principal factor responsible for this complication. Tuberculous and nontuberculous empyema occurred in 20 cases. It seems that postoperative hemothorax is chiefly responsible for the production of nontuberculous empyema and that rupture of cavity at the time of operation is the main factor responsible for the production of tuberculous empyema. There were 23 deaths; the mortality for pneumonectomy was 10.1% and for unilobar lobectomy 5.6%, and no deaths resulted from segmentectomy and wedge resection. Of the 20 early deaths, 7 resulted from shock or cardiorespiratory failure during or within 24 hours after operation. Bilateral cervical vagosympathetic block seemed to prevent such fatalities. Another common cause of fatality was empyema. Death resulted only in patients in whom the indication for surgical treatment was absolute. The status of 252 of the 263 patients who could be followed up to date is satisfactory.

Pneumonectomy, Lobectomy, and Segmental Resection in Treatment of Pulmonary Tuberculosis. E. J. Zerbini, B. J. Fleury de Oliveira and R. Monteiro de Arruda. Rev. paul. med. **46:**325-388 (May) 1955 (In Portuguese) [São Paulo, Brazil].

Between 1946 and 1954, 255 patients with pulmonary tuberculosis were treated with one or more pulmonary resections. Males and females were about equal in number. Most of the patients were between 30 and 40 years of age. Bacilli were present in the sputum of all patients but 18. The patients were observed in three groups of 27, 76, and 152, as they had the operation during the first, second, or third three-year period of this study. Special reference is made to 152 patients who had the operation between 1951 and 1954. Indications for pulmonary resection were: unilateral diffuse tuberculosis (the "destroyed lung") in 14 cases; tuberculoma in 15; atelactasis, fibrosis, and bronchiectasis in 11; tuberculosis of either the lower or the middle lobe in 9; large cavities of upper lobe with bronchial tuberculosis in 17 cases; residual lesion after pneumothorax in 10 cases and after thoracoplasty in 15 cases; tuberculosis in only a lobe or in only a segment in 37 cases; and lesions of the upper lobe associated with lesions of either the lower or the middle lobe in 7 cases. Predominantly exudative tuberculosis was not observed in this group. There were 35 patients subjected to a pneumonectomy; 68 to a lobectomy; 38 to segmental resection; and 11 to a lobectomy combined with a segmental resection. Postoperative complications did not develop in 108 patients. Postoperative diffusion of tuberculosis developed in 10 patients, reactivation of the lesions in 2, bronchial fistula in 23, and empyema in 9. Other complications in nine patients were controlled by antibiotics or by collapse therapy. Clinical cure was obtained in 62 patients after lobectomy (91%), in 30 patients after segmental resection (78%), in 25 after pneumonectomy (71%) and in six after a lobectomy combined with a segmental resection (54%). There were eight deaths. In six patients only was death attributable to the operation. Five patients died after a pneumonectomy and one after a lobectomy, a rate of mortality of 14% and 1% respectively for these operations. There were no deaths after segmental resection alone or in combination with a lobectomy.

The Site of Origin of Lung Cancer and Its Relation to Histological Type. J. B. Walter and D. M. Pryce. Thorax **10:**117-126 (June) 1955 [London, England].

The view that the majority of lung cancers arise in the main bronchi is based mainly on postmortem studies of the disease in its terminal stages when the tumor has, in most instances, attained a large size. In these cases the direct spread and lymphatic metastasis have combined to produce the familiar hilar mass involving lung, bronchi, vessels, and mediastinal structures alike. Gross involvement of the large hilar bronchi is usually present, and this has been assumed to be the origin; it is doubtful whether this assumption is often justified. The authors have long been aware of the great frequency of the peripheral type of pulmonary cancer. In examining 207 resected lung cancers they definitely located the site of origin in 59.4%, and in an additional 18.4% the probable site was found. Th tumors were classified according to the site of origin into thre groups: central, arising in one of the nominate bronchi; inte mediate, arising in a macroscopically visible branch of one the nominate bronchi; and peripheral, arising in one of th minute bronchi or bronchioles. Of 123 definitely located tumor 47.1% were central, 3.3% intermediate, and 49.6% periphera The most distinctive feature of the central tumors was bronchi obstruction; this was present in all cases, and examination the obstructive changes in the lung beyond was found to a useful guide in the location of tumor origin. Peripheral tumo often showed central scarring (55%), and when bronchi involvement was present it was due to invasion either from t primary growth directly or from secondary lymph nodes. T majority of small tumors were central, and it is concluded th the central type produces early symptoms. The giant and lar tumors were mainly of peripheral type indicating that the ons of symptoms occurs at a later stage in the development of t disease. Of those tumors whose site of origin was located, t adenocarcinoma was always peripheral and the polygonal c growths frequently peripheral (86.7%). Squamous-cell tumo were more often central (57.9%) than peripheral (36.8%), whi oat-cell carcinomas were equally divided between the t groups. Comparison between the histology of the 207 surgic cases and a postmortem series of 159 cases gives some id of the surgical selection, and it is concluded that the centr type is favored for resection. Since in this surgical series abo one-half of the tumors were peripheral, the authors believe th the figure for lung cancer as a whole is considerably high than this. They believe that this frequency of the periphe type is a major factor in the low operability rate and po prognosis in lung cancer.

Evaluation of Vagotomy with Gastroenterostomy Perform for Chronic Duodenal Ulcer: Report Based on Five-Year F low-Up of 145 Patients. S. O. Hoerr. Surgery **38:**149-157 (Ju 1955 [St. Louis].

Of 154 patients with chronic duodenal ulcer who underwe subdiaphragmatic vagus resection combined with posteri gastrojejunostomy at the Cleveland Clinic between 1946 a 1949, 145 were followed for a minimum of five years after t surgical intervention. Of these, 118 (81.4%) obtained satisfacto results, which were excellent in 92 (63.4%) and good in (18%). Results were unsatisfactory in 27 patients (18.6%), of whom (about 4% of the total number) were improved in th ulcer symptoms were no longer present; but the patients we dissatisfied with the functioning of the gastrointestinal tra and usually required daily medication, largely because of psych logical factors. Of the remaining 21 patients (8% of the to number), who were therapeutic failures, 12 had recurrent ulcer tion that was proved at a second operation in 8 and by x-r evidence correlated with the clinical picture in 4. One of t 21 patients died from a second operation for ulcer disease another hospital and one died of a mesenteric vascular occlusi possibly related to a large jejunal ulcer; 2 died of other caus Of the remaining 17 patients, all but 3 (2%) are satisfactori controlled at the present time insofar as ulcer symptoms a concerned; this has been achieved in 6 of these patients by second operation and in the other 8 by a medical regime Troublesome side-effects of the operation were infrequent; two patients the dumping syndrome was a problem, and five patients diarrhea that could be attributed to the operati proved annoying. In 134 patients data were available on t postoperative body weight, which suggest that there is postoperative impairment of ability to maintain normal weig Since vagotomy combined with posterior gastroenterostom has a mortality rate of less than 0.5% and few side-effec it is believed that it should continue to be used when surgic intervention is necessary in the poor-risk patient or when t surgeon is confronted with a technical situation renderi gastric resection and closure of the duodenal stump undu hazardous.

Evaluation of Gastric Exfoliative Cytology. D. C. Browne, R. Mitchell, G. Welch and W. Sorrell. Gastroenterology 28: 964-968 (June) 1955 [Baltimore].

The authors are concerned with the gastric brush technique, a rapid method for obtaining gastric material for cytological study, which was described by Ayre and Oren in 1953. Their aim was to ascertain its value for screening and to compare its results with gastroscopy and roentgenography. The 93 subjects of this investigation were hospitalized patients referred to the gastroscopic clinic for study. All patients had been subjected to roentgenographic examinations of the upper gastrointestinal tract prior to admission. Cytological material was obtained by means of Ayre's gastric brush technique, immediately following which gastroscopic examination was performed. This permitted evaluation of the safety of the brush method. Of the 93 patients, 65 (69.7%) showed some evidence of the instrumentation on gastroscopic examination. The lesions occurred as localized hemorrhagic submucosal areas with no superficial breaks, as small excoriated areas with active bleeding, and occasionally as areas from which strips of mucosa appeared to have been removed. Bleeding was never excessive. In 2 patients in whom gastroscopy was performed a week after gastric brushing, no evidence of trauma was noted. Surgical treatment was suggested to the 93 patients and 56 accepted, the remaining 37 being followed on a medical regimen. The present report is concerned primarily with the patients who underwent operation and in whom immediate follow-up evaluation was possible. The authors feel that roentgenographic and gastroscopic examinations, when applicable, remain the most important and reliable methods available today in diagnosis of gastric lesions; the brush technique may assist in establishing a diagnosis of malignant disease, particularly when the mucosal surface is involved and the lesion is within the field of the brush. A positive result of the brush test for malignant cells, or one compatible with malignant disease, indicates a malignant gastric lesion. Negative reports are worthless. Ayre's gastric brush is relatively safe. Although trauma from the brush or instrument occurred frequently, in no instance were there any sequelae of clinical importance. The present series does not consist of early asymptomatic patients but, rather, of hospitalized patients with evident gastric disease who were under better control than outpatient clinic or private patients. In the light of the results obtained, it would scarcely seem practical to apply the Ayre brush method as a screening procedure until many technical refinements have been accomplished.

Study of the Dumping Syndrome in a Series of 100 Gastric Resections for Ulcer. A.-G. Weiss, L. Hollender and Z. Massy. Arch. mal. app. digest. 44:291-305 (March) 1955 (In French) [Paris, France].

In a series of 100 patients who underwent gastric resection for ulcer, 18 obtained poor results, and of this group 9 had the dumping syndrome. In analyzing the factors operating in these patients, it was found that neither sex, age, nor location of the gastric lesion showed correlation with the dumping syndrome, while psychic state, occupation, and quality and duration of convalescence did. Seven of the patients were tense, nervous, and irritable. The more intellectual occupations were better represented in the group than the less. The postoperative health and dietary programs prescribed were scrupulously observed by only one patient, poorly observed by two, and not observed at all by six. None of the patients had allowed sufficient convalescent time for good readaptation. Experimental observations made of the nine patients were not conclusive. In two there was a definite hypokalemia at the onset of attacks, but the administration of potassium did not modify the symptoms with the exception of the sense of fatigue, which diminished after prophylactic intravenous injection of potassium. It would seem that the hypokalemia was the result of early disturbance of carbohydrate metabolism. The other electrolytes were within normal limits. A study of the acidity curve after resection showed no significant difference between patients with and without the dumping syndrome. Dumping syndrome rarely occurs after gastric resection for neoplasm; this appears to be an indication that the syndrome is intimately connected with the neurovegetative imbalance characteristic of the gastric ulcer patient. The point of departure of attacks of dumping syndrome is very likely distention of the jejunum by poorly digested food, but the basic cause of the syndrome remains unknown.

Increased Excretion of Aldosterone Immediately After Operation. J. G. Llaurado. Lancet 1:1295-1298 (June 25) 1955 [London, England].

Surgical trauma is followed by a positive sodium balance and a negative potassium balance. The discovery by Grundy and co-workers in 1952 of a new hormone of the adrenal cortex, now called aldosterone, which has the ability to increase greatly both sodium retention and potassium excretion by the kidney, the subsequent isolation of this hormone, and the determination of its chemical structure have given a new impetus to the investigation of clinical disturbances associated with sodium retention and increased potassium excretion. Having observed previously that aldosterone (electrocortin) was present in large amounts in the urine of a patient suffering loss of potassium, it seemed important to the author to determine whether the potassium loss following surgical trauma could also be explained by increased secretion of the electrolyte-regulating corticoid (presumably aldosterone). He made a search for this corticoid in the urine of patients before and at various stages after surgical operation. By a bioassay designed to detect aldosterone, it was shown that a sodium-retaining and potassium-excreting factor is present in the urine of patients after surgical operations. Some patients excrete this factor before operation, but in all cases the excretion after operation is very much greater than before operation. Evidence is adduced that this activity is due to aldosterone. The increased excretion of electrolyte-regulating corticoid is shown to accompany the sharp potassium loss and the early sodium retention that are common features of the normal response to surgery. Excretion levels of this corticoid correlate qualitatively with the sodium/potassium ratio in the urine of patients before and after operation. Increased production of the electrolyte-regulating corticoid may be one of the factors responsible for the electrolyte changes in the immediate postoperative period. The results of assays with pure crystalline aldosterone are also reported. This steroid is 100 times as strong as desoxycorticosterone when assayed in terms of sodium/potassium urinary deviation in the rat by the present method.

NEUROLOGY & PSYCHIATRY

Physiologic Observations Following Total Hemispherectomy in Man. G. M. Austin and F. C. Grant. Surgery 38:239-258 (July) 1955 [St. Louis].

Right-sided total hemispherectomy with removal of all of the cortex, underlying white matter, and basal ganglions, leaving only the thalamus and hypothalamus, was performed on two women, aged 35 and 28, and two men, aged 28 and 47, with malignant tumors such as astroblastoma, glioblastoma multiforme, and nonspecific glioma. The prime purpose of the operation was an attempt to remove the tumor radically in order to prolong the patient's life in the possibility of a cure. There was no operative mortality, and all patients who already had severe hemiparesis or hemiplegia before the total hemispherectomy regained gross function of the left leg sufficient to walk with some degree of facility. Some movement was regained at the shoulder, and there was also slight elbow flexion, although no finger movement was regained. Electroencephalograms taken before and after the operation showed improvement in normal frequencies and amplitude over the remaining hemisphere after the hemispherectomy. Psychological studies showed relatively little change of memory, and intellectual capacity for concrete facts remained good. There was considerable increase in the latency of response to questions. Most pronounced changes were in the realm of perceptual thought. Quantitative measurement of pain and touch showed that pain sensation was decreased less than touch on the side opposite hemispherectomy. Touch sensation remained grossly impaired, whereas threshold for pain sensation at the end of three months had returned to normal. Thalamic sections made on the brain of one patient who died two and one-half months postoperatively showed complete degeneration of the nucleus ventralis posterolateralis and almost complete degeneration of the nucleus ventralis posteromedialis on the ipsilateral side.

Stilbamidine Treatment of Tic Douloureux. B. Woodhall and G. L. Odom. North Carolina M. J. **16**:222-224 (June) 1955 [Winston-Salem, N. C.].

Woodhall and Odom began to use stilbamidine therapy for treatment of trigeminal neuralgia (tic douloureux) in April, 1953. Based upon observations of the treatment of blastomycosis with stilbamidine at Duke Hospital and the resultant neuropathy, 1.5 gm. of the drug was chosen as being close to the minimum effective dosage. Stilbamidine isethionate, 150 mg., was freshly dissolved in 150 cc. of 5% glucose and distilled water, protected from light by a dark paper covering, and given intravenously over a period of one hour. No shock-like reactions were observed. The course of therapy consisted of 10 daily injections for a total dosage of 1.5 gm. of the drug. The authors found that intravenously administered stilbamidine isethionate controlled the pain of trigeminal neuralgia in 36 of 41 patients in this preliminary series of observations for a period ranging between two years and nine months. The relief of pain was associated with sensory changes over the trigeminal and upper cervical dermatomes that suggest a true chemical neuropathy. In a small percentage of cases, unpredictable formication and paresthesias occurring over the face tended to decrease the potential value of this therapeutic agent. The deferred action of the drug in patients with severe and unrelenting tic pain is a severe trial to both the patient and the physician and may necessitate provisional methods of control before the onset of the chemical neuropathy. Although this drug in its intravenous form may not be the definitive medical therapy for trigeminal neuralgia, it represents a valuable adjunct to the care of this often complex pain syndrome. A continuing study of the influence of stilbamidine, in both its intravenous and its oral forms, upon the course of trigeminal neuralgia should be encouraged.

Latent Epilepsy as a Factor in Tension States. D. W. Liddell, A. A. Robin and C. E. Darby. J. Nerv. & Ment. Dis. **121**:215-222 (March) 1955 [New York].

Pathological tension is present as a symptom in many psychiatric conditions. These tension states are marked by multiple symptomatology. The patients complain of feeling on edge, of being unable to relax, of restlessness, of anxiety, of their thoughts going round, and of insomnia, headaches, irritability, and exhaustion. The authors show that some tension states are in fact epilepsy, possibly latent at the time of examination. It should be noted that the epileptic prodrome is also a tension state, lasting a day or so and being relieved by the epileptic discharge, while in the cases under review this discharge failed to occur and tension continued for weeks or months. The finding that first drew the attention of these authors to the possibility that latent epilepsy formed a possible basis of tension states, was the third or lower subharmonic response to photic stimulation, which, in their view, may be an indication of latent epilepsy, even in the presence of an otherwise normal record. Responses to photic stimulation were reviewed and revealed that third or lower subharmonics were usually associated with further evidence of epilepsy in the electroencephalogram. When subharmonics occurred alone the patients in question showed tension as a prominent symptom. The authors present the histories of four patients with prolonged tension states in whom electroencephalographic studies revealed a third or lower subharmonic response to photic stimulation as the only irregular finding at routine examination. The first patient presented a tension state with a long history of stress. In this woman the constitutional aspect was obvious as her daughter was epileptic. Her own complaints preceded her first fit by about three years. Photic stimulation alone reproduced
her symptoms and when continued produced myoclonic
ments, visual hallucinations, or a fit. Phenobarbital provid
adequate safeguard against this with some clinical improve
A satisfactory social solution was found. The second cas
emplifies the interaction of exogenous factors with a
epileptic constitution in the production of tension. Once suff
stress had occurred, tension seemed to be self-perpetuati
stillbirth produced the initial anxiety and tension, which
continued for two years. Photic stimulation also acted
source of external stress. This produced a low-frequency
rhythmia in the electroencephalogram. However, when the
was removed the dysrhythmia continued and increased in
tude in a self-perpetuating manner and was accompanied
cally with increasing uneasiness. A major fit eventually res
with temporary relief of tension. The third patient also
plained of tension. While the external environment must
played a large part in exciting it, environmental manipu
offered little hope. Temporary improvement was produc
manipulation of the internal environment and the patien
learned to do this himself with alcohol. The last patient
tension state in which the clue offered by the third subharn
made the psychological tension comprehensible in physical
as an epileptic prodrome. The symptoms were produced by
reaction to environment and abated when the environmen
changed. Treatment for epilepsy or environmental manipul
may be useful in the treatment of this group of tension sta

Value of Fractionated Encephalography. G. J. Melot a
Potvliege. Acta clin. belg. **10**:6-19 (Jan.-Feb.) 1955 (In F
[Brussels, Belgium].

The authors performed over 300 pneumographies, usin
encephalography and ventriculography, in patients with ce
arachnoiditis or tumors above or below the tentorium.
experiences led them to use the technique of fractionate
cephalography as described by Robertson and by Lindg
the method of choice. A moderate quantity of air is used,
can be adapted to the individual patient and directed t
the particular region to be examined in each case. The tech
is a safe one. When properly practiced, it yields satisf
information on the external surface and the internal structu
the brain. It also permits ascertaining the permeability
cerebrospinal fluid canals, which knowledge is of prime in
ance in the diagnosis and treatment of arachnoiditis and
tumors. Seven illustrative case reports are presented. In
patients, fractionated encephalography gave diagnosis of
specific optic chiasm and pontocerebellar arachnoiditis, ad
meningitis of tuberculous origin, cerebellar hemangioblas
astrocytoma of the brain stem, and acoustic schwannoma.

**Superior Hemorrhagic Polioencephalopathy (Wernicke's
ease) in Hyperemesis Gravidarum and in Carcinoma of Sto**
W. J. C. Verhaart, C. B. F. Daamen and J. A. M. Van
Nederl. tijdschr. geneesk. **99**:1410-1414 (May 14) 195
Dutch) [Haarlem, Netherlands].

The symptoms of superior hemorrhagic polioencephalo
which were first described by Wernicke in 1881, are ano
vomiting, nystagmus, ophthalmoplegia, impairment of me
ataxia, weakening or abolishment of tendon reflexes, disor
tion, and, finally, coma. It is generally assumed that the dise
usually caused by chronic alcoholism, although Wernicke'
patient was not an alcohol addict, and the disease is also
in patients with gastrointestinal disturbances. Of the four pa
whose histories are described in this paper, two had canc
the stomach and two had hyperemesis gravidarum. The foo
take was probably deficient in all four of these patients. Fe
experiments in pigeons revealed that lack of vitamin B_1 r
in conditions similar to those seen in patients with sup
hemorrhagic polioencephalopathy. Furthermore, experienc
Japanese concentration camps also indicated that vitami
deficiency may cause superior hemorrhagic polioencephalop

Neurosurgical Experiences with Diabetes Insipidus. E. H. Botterell and W. J. Horsey. Neurology 5:449-460 (July) 1955 [Minneapolis].

The hypothalamohypophyseal system regulates the rate of excretion of water in the urine by the elaboration of the antidiuretic hormone (Pitressin). Lesions of the supraoptic nuclei, of the supraopticohypophyseal tracts, or of the neurohypophysis are capable of causing diabetes insipidus in humans, and, experimentally, in animals. Polyuria and polydipsia are readily controlled by the parenteral administration of Pitressin. A series of patients with posttraumatic diabetes insipidus is described. The incidence of this complication is 0.44% of 1,148 cases of craniocerebral injury admitted to the Toronto General Hospital in six years. Of seven patients whose cases followed accidental injury, six had symptoms after a latent period of about eight days, while one had polyuria on the day of injury. At autopsy, the latter showed a recent hemorrhage into a cystic space in the infundibular process of the neurohypophysis. Three patients with intracranial space-occupying lesions are presented to show how the hypothalamohypophyseal system may be disorganized with the production of diabetes insipidus. Associated neurological and endocrine disorders are described. The parenteral administration of Pitressin conveniently and effectively controls the diabetes.

GYNECOLOGY & OBSTETRICS

The Treatment of Eclampsia (Imminent or Actual) by Continuous Conduction Analgesia. R. Bryce-Smith and E. O. Williams. Lancet 1:1241-1244 (June 18) 1955 [London, England].

The histories of six women with eclampsia who were treated by continuous conduction block are described. Caudal, lumbar extradural, and spinal approaches were used in the six patients. The authors gained the impression that a block by the caudal route is of little value. The blood pressure is controlled most effectively by continuous spinal analgesia, but this carries the risk of meningitis. A continuous lumbar extradural block is safer and will give almost as good results for 24 hours as a spinal. Whichever method is chosen, there is a chance that labor will be retarded by a block that reaches the optimal level (varying from patient to patient) for controlling the blood pressure. In such instances, it is suggested that, rather than lower the level of the block, a Pitocin drip should be established to stimulate normal uterine function. The improvement in the appearance of an eclamptic patient treated with conduction analgesia is striking; and, since heavy sedation is unnecessary, maternal morbidity is reduced and the fetus offered a better chance of survival. On these grounds a continuous conduction block in selected cases is preferable to treatment with sedatives; but, since a postpartum diuresis can be expected to follow delivery in most cases, eclamptic oliguria by itself does not necessarily provide a specific indication for block therapy. At present the authors do not feel justified in suggesting that a conduction block be used in all cases of severe toxemia; but in desperate cases block therapy has much to offer. Nevertheless such treatment presents a disadvantage, since it is necessary to provide constant supervision throughout the 24 hours by an anesthetist and an obstetrician, who must always be at hand.

Rupture of the Uterus: A Report of 50 Cases Which Occurred in Two and a Half Years at Baragwanath Hospital, Johannesburg, South Africa. D. W. P. Lavery. J. Obst. & Gynaec. Brit. Emp. 62:454-463 (June) 1955 [London, England].

Rupture of the uterus is of particular interest to obstetricians in South Africa who practice among the Bantu people. The author reviews observations on 500 Bantu women with uterine ruptures. These ruptures occurred in a period of 30 months among 6,857 deliveries, a ratio of 1:137 (compared with 1:2,233 in Britain). The average Bantu child weighs only slightly less at delivery than does the average European child, but the pelvis of the Bantu woman is definitely smaller than that of the European woman. All but four women were multigravidas, but, contrary to the generally accepted concept of the grand multipara being more liable to this accident, the greater number of patients (31) had been pregnant four times or less. Complete rupture, that is, the form that affects all uterine layers and communicates with the general peritoneal cavity occurred in 38 of the patients; incomplete rupture, involving only the muscular coat occurred in the other 12 patients. Primary rupture occurred in 45, and secondary rupture, through previous cesarean section scars, occurred in the other 5 women. The site of rupture was more often the anterior lower segment and was transverse in direction. The causes of uterine rupture include obstructed labor, malpresentations, disproportion, and, in the South African Bantu woman, premature bearing-down on an incompletely dilated cervix. The characteristic sudden sharp pain, with cessation of labor pain, occurred in 41% of cases. The fetus could be palpated "under the skin" in most patients, and a constant feature in primary spontaneous ruptures was the presence of blood in the urine. Treatment consisted of repair of the uterus in 28 of 50 patients and hysterectomy in 11 patients, and in 11 patients no operation was possible. Antishock measures, blood transfusion under pressure, and corticotropin by intravenous drip therapy all formed adjuncts to surgery. The mortality rate was 32%; all but one of the maternal dealths occurred in women with complete rupture. Causes of death were shock and hemorrhage in 11 women, peritonitis in 3, pulmonary embolism in one, and gas gangrene in one. Of the 16 patients, 6 died within five hours of admission.

Endometriosis: The Results of Conservative Surgery. D. B. Whitehouse and A. Bates. J. Obst. & Gynaec. Brit. Emp. **62:**378-384 (June) 1955 [London, England].

For the purpose of this study, conservative surgery was defined as an operation for endometriosis in which ovarian tissue was conserved. Between Jan. 1, 1943, and Dec. 31, 1948, 100 patients were so treated at the Birmingham and Midland Hospital for Women. The follow-up interval, therefore, varied from 6 to 11 years. The diagnosis of endometriosis was confirmed in each case by histological examination of tissue removed at operation. On the basis of the operative procedures, the women are classified into three groups. The 85 women of group one were subjected to resection of pelvic endometriosis with preservation of the reproductive function; the 9 of group two were subjected to total hysterectomy with conservation of ovarian tissue; and in the 6 of group three extra-abdominal endometriomas were excised. Follow-up was possible in 46 of the 85 patients in group one; in 32 of these 46 the symptoms disappeared completely; 7 had mild recurrence of symptoms; and the other 7 had severe recurrence requiring further treatment. More complete removal of all foci of endometriosis at operation would probably have reduced the recurrence rate. Of 35 patients with pelvic endometriosis in whom reproductive function was preserved, 16 became pregnant, producing 24 children. The fertility rate was not appreciably influenced by the extent of the operation or the age of the patient when under 41 years. Follow-up of those in whom recurrences had been treated suggested that surgery was preferable to radiotherapy in women over 30, because of the severe menopausal symptoms associated with the latter. No evidence of recurrence was found in five patients in whom endometriosis had been treated by hysterectomy preserving ovarian tissue. It is suggested that, if radical surgery is indicated, complete castration is not necessary to prevent recurrences, provided the uterus is removed.

Prolapse of a Fallopian Tube into the Vaginal Vault Following Hysterectomy. J. W. Funnell and J. W. Kelso. South. M. J. 48:681-686 (July) 1955 [Birmingham, Ala.].

The prolapse of a fallopian tube into the vaginal vault after hysterectomy is an unusual complication. The prolapsed tube not infrequently is mistaken for a malignant lesion of the vagina. The five cases presented were collected from several sources. All were seen in consultation, but only one of these patients was treated by the authors originally. The myth that this complication occurs only after vaginal hysterectomy is disproved by the fact that two of the five cases presented occurred after abdominal hysterectomy. The symptoms of prolapse of a fallopian tube into the vagina after hysterectomy are usually a profuse, watery, often bloody, vaginal discharge and varying degrees of lower abdominal discomfort most often localized to the side of the prolapsed tube. In some instances, especially in cases of long standing, the patient may be entirely symptom-free. The diagnosis should be suspected when there is a red, granular, polypoid mass projecting into the vagina from the vaginal cuff. It must be differentiated from proliferative granulation tissue and a malignant lesion of the vagina, the two conditions with which it is most often confused. Final diagnosis depends upon biopsy and histological examination of the tissues. Treatment is rather simple and one of several methods may be used. The mass may be excised and the base cauterized, or it may be excised with the cautery loop. However, with these methods, healing of the defect in some instances requires a considerable period of time. Because of this, the authors prefer to grasp the mass with a hemostat and make an elliptical incision through the vaginal cuff. Then, with slight traction, they deliver the tube into the vagina, ligate it as high as possible, and excise the distal portion. The defect in the vaginal cuff is then closed with interrupted sutures. If there is a vaginal infection, it should be treated prior to the above procedure.

DERMATOLOGY

Alseroxylon in the Treatment of Pruritic and Psychogenic Dermatoses. R. J. Ferrara and H. Pinkus. A. M. A. Arch. Dermat. 72:23-28 (July) 1955 [Chicago].

The coincidental improvement or disappearance of psoriasis has been noted in patients receiving treatment with Rauwolfia for arterial hypertension and psoriatic arthritis. Favorable results have also been reported in a series of patients with various dermatoses affected by a psychogenic or emotional tension factor who were treated with reserpine (Serpasil). Alseroxylon (Rauwiloid), another Rauwolfia derivative, was used by the authors in treating 47 patients with various dermatoses in which tension factors or psychogenic stimuli were prominent. This product, which is a concentrate of the active alkaloids, extracted from the root of Rauwolfia serpentina, was chosen on the assumption that greater clinical benefit may be derived from a mixture of alkaloids than from a single alkaloid. It contains all the desirable hypotensive alkaloids found in the root, but it does not contain the less desirable yohimbine-like alkaloids. Reserpine and the recently isolated and identified rescinnamine account for about 60% of the hypotensive potency of alseroxylon; the remaining 40% is attributed to other as yet unidentified alkaloids. The daily doses of alseroxylon varied from 4 to 8 mg., depending on the age of the patient and the severity of the disease. The treatment was given in courses of from two to six weeks, and periods of placebo therapy were alternated with periods of alseroxylon therapy in 19 patients, to permit evaluation of the therapeutic effect of alseroxylon as compared with placebo tablets of the same appearance. Local therapy either was omitted or included a bland preparation; when used, it was continued without change throughout the course of alseroxylon and placebo therapy. No other therapy was given. All the patients had chronic dermatoses, mostly of a pruritic nature, that were either in a state of exacerbation or poorly controlled; sedatives, local antipruritics, antihistamines, corticosteroids, and x-rays were among the forms of treatment that had previously been tried. The patients were reexamined at weekly and biweekly intervals and were questioned about their subjective symptoms. Varying degrees of relaxation, tranquilization, and mild sedation were reported by all. Itching was relieved in all the patients with pruritic conditions, except for the one who had urticaria. Subjective effects from alseroxylon were noted by the patients within three to seven days. The maximum therapeutic response was obtained in one to four weeks. Placebo substitution led to the return of cutaneous symptoms, also within a period of one to four weeks. The side-effects such as fatigue, drowsiness, and nasal congestion were generally of little importance except in one patient who refused further treatment because of marked fatigue. The results obtained in these patients, 36 of whom were foll either to complete recovery or long enough to permit com tive evaluation of alseroxylon and the placebo therapy, to show that alseroxylon possesses qualities of decided in the treatment of dermatoses in which a psychogenic is prominent.

Livedo Reticularis with Summer Ulcerations. M. Feldak A. Hines Jr. and R. R. Kierland. A. M. A. Arch. Derma 31-42 (July) 1955 [Chicago].

A study of 12 women, aged 17 to 54, with idiopathic reticularis seen at the Mayo Clinic during the last 10 yea disclosed the existence of a new syndrome in which lived cularis is associated with ulcerations of the legs occurrin marily during the warm spring and summer months inste during the cold fall and winter months as usual. Idio livedo reticularis may be defined as a condition of the characterized by a reddish-blue, mottled, reticular, or bl discoloration. It had been present in these patients to a va degree for several weeks, months, or years before the on the ulcerations and was usually worse in the winter th other times. The present histories of the patients, which remarkably similar, showed the following typical sequen events: edema of the feet and ankles, developing in the or summer and followed by the appearance of bluish-r farctive areas over the ankles, dorsa, and soles of the fee on the anterior aspect of the legs. These infarcts eithe appeared spontaneously with rest in bed or were succeeded two or three weeks at the same site by ulcerations result drainage of serous, serosanguineous, or purulent material ulcers were extremely painful and resistant to treatmen they would eventually heal, leaving an atrophic, pigmented The entire course from the onset of the infarcts to ulce and healing would take from one and one-half to three m new ulcerations would develop continually during the sur but with the return of cold weather the tendency to recu ceased and the ulcers that were present healed more rapid that the patient became free of ulcerations or markedly The results of physical examination of the patients, apart the ulcerations and the presence of livedo, were essentiall mal in every instance. Histopathological studies reveale clusive changes in the arterioles and veins of these patient were similar to those in the arteries and veins of five other winter ulcerations accompanying idiopathic livedo retic No evidence was found to indicate that tuberculosis, syphi periarteritis nodosa was a causative factor in any of these None of the patients, eight of whom were housewives employed in an occupation in which she was exposed to exc heat or cold, and in none was occlusive arterial disease suspected or demonstrated. A combination of medical ment employing mild local antiseptic dressings, powdered cells, rest in bed with elevation of the extremities, elastic portive bandages to prevent edema, and a trial of the methonium drugs, seems to be the therapeutic method of c for patients with this syndrome. Bilateral sympathectomy, in four patients, produced little permanent benefit.

Curettage as a Method of Treatment for Plantar Warts. Seale and J. B. Richardson. South. M. J. 48:575-577 (June) [Birmingham, Ala.].

The operative field is cleansed with 70% alcohol and the area is sprayed with ethyl chloride, and, when blan occurs, a 26 gauge one-half inch hypodermic needle is c with one thrust completely under the wart. About 2 cc. of procaine solution without epinephrine is then injected slowly, since pain increases with the rapidity of the inje When anesthesia is complete the keratinized surface of the is removed, and then with a curet the globules of verr tissue are shelled out, leaving a cavity with overhanging a glistening fascial floor and firm side walls. The overha edges are removed with small curved scissors and the w filled with 5% Mercurochrome. Profuse bleeding is contr by a pressure dressing held in place by adhesive tape compl encircling the foot. The patient is instructed to remove the age the following day and apply an antibiotic ointment and a simple dressing twice daily until healing occurs. A consecutive series of 140 patients (total of 155 lesions) were treated in this manner and followed for at least one year. There were 15 recurrences in this group. The method yielded a higher percentage of cures than did the other popular forms of treatment, such as radiotherapy, cauterization, and electrodesiccation.

OPHTHALMOLOGY

Studies on the Effect of Chloromycetin to Trachoma, Especially on the Comparison of Various Concentrations of Ointment. M. Mikuni and A. Tsuchiya. Acta med. et biol. 2:755-771 (Dec.) 1954 (In English) [Niigata, Japan].

This report is concerned with the use of chloramphenicol (Chloromycetin) ointment, in various concentrations, in the treatment of trachoma in nearly 800 Japanese children. A chloramphenicol ointment of 5% concentration was used in 85 children, a 2% ointment in 185 children, a 1% ointment in 234 children, a 0.5% ointment in 130 children, a 0.25% ointment (first five weeks) plus a 3% ointment in 77 children, and a 0.1% ointment (first five weeks) plus a 1% ointment in 55 children. The ointments were applied once a day, and examinations were made once a week. The severity of the trachoma lesions was graded according to MacCallan's three-stage classification to which the group of patients with doubtful trachoma was added. The authors compare the results obtained with the different concentrations of chloramphenicol in the various stages of trachoma, particularly with regard to the length of treatment required. With regard to the cure rate in all cases, they state that with 5% ointment 52.3% of the children with trachoma were cured in 8 weeks and 85.3% in 20 weeks; with the 2% ointment the respective figures were 54.2% in 9 weeks and 81.5% in 20 weeks; with 1% ointment, 51.3% in 10 weeks and 76.2% in 20 weeks; and with 0.5% ointment, 51.1% in 11 weeks and 71.8% in 20 weeks. The 0.25% ointment applied for the initial 5 weeks gave only 5.2% cures, which increased to 55.8% in 11 weeks by the substitution of 3% ointment and reached 83.2% in 20 weeks. The 0.1% ointment applied for the initial 5 weeks gave a 3.6% cure rate, which increased, as the 1% ointment was substituted, to 51.3% within 12 weeks and reached 76.3% within 20 weeks. In general, the higher concentrations of chloramphenicol produced the better results, but, even with 0.5% ointment, if applied continuously and over a long period, satisfactory results could be obtained. The advantages of trachoma therapy with chloramphenicol ointment are that even high concentrations cause no irritation or other undesirable secondary effects and that the ointment is very stable. The authors feel that chloramphenicol ointments of 1% or 2% concentration are best for practical use.

Etiology and Therapy of Retinal Vascular Occlusions. B. Anderson and W. Vallotton. A. M. A. Arch. Ophth. 54:6-12 (July) 1955 [Chicago].

The authors present their experiences in 120 patients observed during the last decade. In arterial occlusion the criteria for inclusion in the study consisted of the appearance or persistence of the characteristic cherry-red spot. On the venous side, the standard for inclusion in the study was clear-cut obstruction of a branch by a rigid artery or the characteristic overripe smashed-tomato appearance of the central venous trunk occlusion. The authors feel that in many instances one could make a reasonable assumption of a correlation between the retinal lesion and some other factor in the history or examination that would permit the division of these cases into etiological groups. Where the diastolic blood pressure was above 100 mm. Hg and the patient over 50, classification was entered under the hypertensive-arteriosclerosis column. Likewise, when there was a clear-cut history of rheumatic fever with other residual evidences of such an infection, the authors felt that there most probably was a causal relationship between this past disease and the occlusion. Therapeutic agents are available that are presumed to relax vasospasm, and anticoagulants that reduce the chances of further thrombosis. The problem lies in bringing these agents into effective use in properly selected cases. Treatment is recommended for all arterial occlusions seen within the first week and for all venous occlusions seen within the first month after the onset. There was no evidence of therapeutic effect on the arterial occlusion of hypertensive-arteriosclerotic origin, but comparative cases suggested that therapy might be beneficial in venous obstructions. Treatment seemed to be most effective in the infectious and postinfectious group in both the arterial and the venous obstructions; two of four arterial occlusions improved under therapy while no improvement was noted in six untreated cases. The authors feel that anticoagulant therapy is justified in both arterial and venous retinal occlusions, that the results in the hypertensive-arteriosclerotic group will be poor, but that in the occlusions associated with infectious processes therapy adds appreciably to the restoration of function.

INDUSTRIAL MEDICINE

Edathamil Calcium-Disodium in Treatment of Occupational Lead Poisoning. A. Zambano and L. Rossi. Riforma med. 69: 398-404 (April 19) 1955 (In Italian) [Naples, Italy].

Good results in treating lead poisoning with edathamil calcium-disodium (calcium disodium salt of ethylenediaminetetraacetic acid) were obtained in six lead workers who were given the drug intravenously in a 20% hypertonic solution in daily doses of 2 gm. for seven consecutive days. Some patients received a second course of treatment after a seven day treatment-free period. No side-effects were noted. The urinary excretion of lead increased and that of coproporphyrin decreased progressively, while the lead blood levels were changed only slightly. Edathamil calcium-disodium acts to make a lead complex by exchanging the calcium contained in its molecule for lead to form a chelate, which does not have the toxic action peculiar to the free metal. The effectiveness of edathamil calcium-disodium in lead poisoning is definitely greater than that of other agents that have been used for the purpose, but greater clinical experience with the drug is needed.

Problem of Rhinitis and Asthma in Bakers. C. Pestalozzi and U. W. Schnyder. Schweiz. med. Wchnschr. 85:496-501 (May 21) 1955 (In German) [Basel, Switzerland].

Of 159 bakers, 42 showed symptoms of respiratory allergy. All 42 had allergic rhinitis, and 6 also had bronchial asthma. A familial tendency to respiratory allergy was observed in 12 (28%) of the 42 bakers, while such a tendency was observed in only 9 (8%) of the 117 bakers without allergic symptoms. Young people with a familial tendency to asthma or rhinitis should be informed about their predisposition to respiratory allergy before they start their training as bakers. In all 159 bakers scratch tests were performed with the flour used in the bakeries where they worked, and intracutaneous tests were carried out with an extract of rye and wheat. Of the 36 patients with allergic rhinitis alone, 24 (66%) had a positive reaction to the tests with the flour used in the bakeries where they worked or with the extracts of wheat or rye. The clinical aspect of the rhinitis, with short dry attacks of sneezing and production of an abundant watery secretion (rhinorrhea), as well as the results of the skin tests indicated that rhinitis in bakers is an allergic rhinitis caused by the flour they have to handle, while still other causative factors in addition to the various species of flour may be responsible for the occurrence of asthma in bakers. Most of the bakers examined showed their first symptoms of rhinitis after an average period of 12.7 years of sensitization. The intensity of the rhinitis remained unchanged for years and even decades in more than two-thirds of the authors' cases. In the six patients in whom the rhinitis was associated with asthma, the symptoms of asthma occurred for the first time after an average 18 years' duration of rhinitis. A partial or total spontaneous desensitization after a 14 to 15 years' duration of the rhinitis occurred in 4 of the 42 patients. Plimasine (a proprietary compound of tripelenamine [Pyribenzamine] hydrochloride and a sympathomimetic drug), pyrilamine (Neo-Antergan), and Synopen (N-dimethylaminoethyl-N-*p*-chlorobenzyl-α-amino-pyridine hydrochloride) were used for the symptomatic treatment of mild flour rhinitis in patients whose work capacity was not reduced. In incapacitated bakers with severe rhinitis specific desensitization should be carried out in addition to symptomatic treatment.

Rheumatoid Arthritis in Males: An Epidemiological Study of a Welsh Mining Community. W. E. Miall. Ann. Rheumat. Dis. 14:150-158 (June) 1955 [London, England].

Caplan pointed out in 1953 that some coal miners with rheumatoid arthritis and with pneumonoconiosis have characteristic chest x-rays. An epidemiological investigation of this new syndrome showed that this nodular lung fibrosis was associated with rheumatoid arthritis in more than 50% of cases; it also suggested that the prevalence of rheumatoid arthritis was increased among men with complicated pneumonoconiosis. To determine whether the progressive massive fibrosis of complicated pneumonoconiosis was a causal factor in arthritis, a survey of rheumatoid arthritis patients was undertaken in a Welsh mining valley, in which progressive massive fibrosis was common among the miners. Immediately before an x-ray survey was started in the valley, a census was taken of the population and during this census a note was made of all persons said to be suffering from any form of arthritis. Ninety percent of the complete population over the age of 15 was subsequently x-rayed, and each individual was asked whether previously or now he had painful swellings of the small joints of the hands or feet. Medical practitioners and the rheumatism clinic provided lists of patients with rheumatoid arthritis. All patients with rheumatoid arthritis found from these four sources were asked to submit to x-ray examination of chest, hands, and feet and to a differential agglutination test. The survey showed that, though the prevalence of rheumatoid arthritis among all patients with massive fibrosis is about 2.7%, compared with 0.6% among miners without massive fibrosis, the prevalence of the disease in miners does not differ significantly from that among nonminers, and therefore it is unlikely that massive fibrosis predisposes to rheumatoid arthritis. It is concluded, therefore, that neither exposure to dust nor the lung changes of complicated pneumonoconiosis play a causal role in rheumatoid arthritis. Heredity seems to play an important causal role in rheumatoid arthritis; this is also true of Caplan's syndrome and of patients with the characteristic Caplan chest x-ray findings without arthritis. There seems to be an inherited abnormality of tissue reaction, not confined to the skeletal system, in those with, or presumably liable to develop, rheumatoid arthritis. This hypothesis would account for the numerous descriptions of cases of rheumatoid arthritis accompanied by active tuberculosis that have appeared since Poncet described tuberculous rheumatism in 1902, but it does not confirm Poncet's view that tuberculosis is a cause of rheumatoid arthritis.

THERAPEUTICS

Protoveratrine in the Treatment of Arterial Hypertension. R. Tricot, A. Rozsa and P. de Boislambert. Semaine hôp. Paris 31:2045-2049 (June 10) 1955 (In French) [Paris, France].

A French preparation of the maleate salts of protoveratrines A and B in tablet form was given orally to 20 patients with arterial hypertension, 7 of whom were treated ambulatorily while 13 were hospitalized. Treatment was instituted with a dose of 1 mg. daily in four divided doses (1 tablet containing 0.5 mg of the drug), in order to determine the patient's sensitivity to the drug. This daily dose was increased to 1.5 mg. at the end of the first week of the treatment, and this dose was increased further to 2 mg. or 3 mg. only in exceptional cases in which the patients did not show sufficient response to the dose of 1.5 mg. per day. Caution seemed to be justified for two reasons. Digestive disturbances, such as heartburn, nausea, and abdominal pains, may be associated frequently with larger doses and may require discontinuation of the drug. They can be avoided by giving the drug after meals and by large doses. A sudden severe drop of the arterial pre occurred in one of the authors' patients after he had the second tablet, and it was associated with general disco and a sensation of great weakness requiring rest in the r bent position. It seems that the excessive susceptibility of c patients to the drug depends on the dose of the drug. Be of the authors' precautions concerning the dose, distur of rhythm that had been reported by other workers di occur. A large number of patients responded favorably drug by a drop of from 35 to 45 mm. Hg of the max systolic pressure and an average drop of from 15 to 20 Hg of the diastolic pressure. The effect of the drug b apparent within several hours, but the maximum effec reached about the end of the first week of the treatmen more rapid the effect of the drug, the shorter was its dur Fractionated doses and prolonged periods of treatmen therefore, required. The follow-up of the patients wa short to permit any definite conclusions concerning late of the treatment.

Treatment of Bronchopulmonary Moniliasis with CM J. W. MacIntosh Jr., J. D. Gray and C. M. Jones. (M. A. J. 72:903-907 (June 15) 1955 [Toronto, Canada].

A new analogue of chloramphenicol labelled CMA 37, had been shown to possess fungicidal properties in vitr given its first clinical trial in a 32-year-old woman with br pulmonary moniliasis. She complained chiefly of pains chest, cough, and loss of weight. Tuberculosis and carcinoma were considered in the differential diagnosi laboratory studies showed a heavy growth of organisms cl as Candida albicans, and this, together with the clinic radiological findings, established the diagnosis of bronc monary moniliasis. Various remedies were tried but fa check the steady deterioration that was taking place condition. The use of CMA 37, therefore, seemed to b ranted, although little was known of either its therapeutic tiveness or its toxicity in man. Treatment was starte three doses of 1 gm. on the first day, then 250 mg. three a day for the next, and then the dosage was increased to 5 three times a day. It was reduced again to 250 mg. three a day for the final two days. These alterations in dosag prompted by the appearance of frequency, dysuria, and turia believed to be side-effects of the antibiotic. The op oral dosage will undoubtedly have to be determined acc to the requirements in each case. The patient began to in almost at once, and six weeks after treatment she was cough and dyspnea; she had gained 16 lb. (7.3 kg.), a feeling of well-being had returned. CMA 37 may well to be as effective against the mycoses as penicillin is the gram-positive bacteria, but since it is an analogue of amphenicol, it should not be used indiscriminately. It co a nitrobenzene ring and, if its use is to be prolonged, the picture should be examined frequently. It may also ha irritating effect on the bladder, as suggested by the hem seen in this patient. No permanent damage resulted fro complication, however, for both the blood urea and the were normal on later examination after the patient had re to her ordinary activities.

Cortisone: Third Element in the Treatment of Brucellosis liminary Report. F. Corelli. Policlinico (sez. prat.) 62:4 (April 11) 1955 (In Italian) [Rome, Italy].

In addition to tetracycline and the specific vaccine, cor or hydrocortisone has been used in the treatment of bruce The combined administration of the antibiotic and hyd tisone resulted in the rapid and surprising improvement patients with this condition. The schedule of therapy was 8 (20 mg. every six hours) of hydrocortisone on the first 60 mg. (20 mg. every eight hours) for three days there 40 mg. (20 mg. every twelve hours) for two to three days 20 mg. for two to three days. Eventually, 10 mg. may be for a few additional days, but often this is not nece Tetracycline was given concurrently in daily doses of

0.5 gm. every six hours) for 30 to 40 days together with 0.5 to 1 gm. of vitamin C orally or by injection and vitamin B complex to prevent eventual side-effects of the antibiotic. Within 18 hours after hydrocortisone therapy was started, fever subsided definitively, and the profuse sweating, headache, and muscular and articular pain disappeared, while the patients' general condition, tone, appetite, and energy were restored. The therapy was well tolerated, and reactions of the Herxheimer type and water retention were not observed. The antibody formation was not influenced and the agglutinin titer increased from a pretreatment value of 1:1,600 to 1:6,400 after 6 days and 1:12,000 after 15 days of treatment. Although tetracycline remains the main agent in the treatment of brucellosis, the author's experience indicates that its combination with hydrocortisone shortens the treatment period and gives results that are far superior to those obtained with the antibiotic alone and with the specific vaccine. Further clinical experience is needed to determine whether this combined therapy is effective also in preventing the frequent relapses of patients with brucellosis.

Combined Treatment with a Chloramphenicol Ester and Streptomycin in Melitococcic Infection. G. Gambusi. Riforma med. 59:459-460 (April 23) 1955 (In Italian) [Naples, Italy].

A preparation containing chloramphenicol succinate, dihydrostreptomycin, and streptomycin sulfate was given parenterally to 15 patients with acute brucellosis, most of whom had had no previous treatment. The average daily dose was 1.5 gm. of chloramphenicol succinate and 0.75 gm. of dihydrostreptomycin and streptomycin sulfate for 9 to 17 days. The therapy was well tolerated, and general untoward reactions were not observed even in the one patient who was given the drug for 17 days. In this patient the fever subsided on the 16th day of treatment. Recovery was prompt and was still present in all but two patients eight months after the treatment was ended. The two patients in whom a relapse occurred a few weeks after the completion of treatment were given vaccine therapy with good results. This new combination is to be kept in mind when treating patients with acute brucellosis, because it is devoid of side-effects and also because the relapse rate is lower than that following treatment with other antibiotics.

Contribution to the Study of the Mechanism of Action of Antibiotics: Variation and Disappearance of Pathogenic Capacity Independent of Proliferative Capacity of a Micrococcus (Staphylococcus). H. Hinglais, M. Hinglais and Y. M. Langlade. Presse méd. 63:989-991 (June 25) 1955 (In French) [Paris, France].

The bacteriostatic power of an antibiotic agent is merely a crude criterion of its efficacy. The authors' studies on a virulent strain of Micrococcus aureus showed that, under the influence of different antibiotics, it was possible for the organism's pathogenicity to disappear before its proliferative capacity was blocked. This dissociation of effect would explain the disparity sometimes seen between antibiotic activity in vitro and in vivo. The appearance of mutations differing from the mother strain by the absence of a single enzyme has been reported in the literature, but there has been no mention of lasting disappearance of the pathogenic capacity. The phenomenon is of theoretical interest, for the evaluation of the hypothesis strongly suggested to the authors that there occurs a fixed and transmissible cytochemical alteration of the bacterial structure from the direct action of the antibiotic. This change manifests itself in a slight modification of the enzymatic equipment.

PATHOLOGY

Erythrocyte Glycolysis in Hemolytic Disease. J. W. Hollingsworth. J. Lab. & Clin. Med. 45:920-925 (June) 1955 [St. Louis].

Blood in vitro utilizes glucose, and blood containing large numbers of reticulocytes exhibits increased glucose utilization as well as demonstrable oxidative metabolism. The present study is concerned with the glycolytic rates of erythrocytes obtained from subjects with hemolytic disease and other diseases associated with reticulocytosis. It was undertaken as an investigation of the relationship of reticulocytosis and maturity of red blood cells to the glycolytic activity of blood. It was also hoped that such a study might detect some gross metabolic defect in the erythrocytes of patients with hereditary hemolytic syndromes. The mean glycolytic rate in vitro of red blood cells from 28 normal subjects and miscellaneous hospital patients was 43 (±8.8) mg. of glucose per 100 ml. of packed blood cells per hour at body temperature. The glycolytic rate of erythrocytes from 14 patients with hemolytic diseases was increased. In general, the increase in glycolytic rate was proportional to the number of reticulocytes present. There were some instances of increased glycolysis without marked reticulocytosis. Serial studies during subsiding reticulocytosis were performed on a patient with hereditary spherocytosis and on two sisters with megaloblastic anemia of pregnancy. In these subjects the relationship between glycolytic rate and reticulocytes was not exact. The data suggest that, even in the absence of reticulocytes, the gylcolytic rate in patients with hemolytic disease may be a rough index of mean age of erythrocytes and, indirectly, of erythropoiesis.

Arteriosclerotic Occlusion of Cerebral Arteries: Mechanism and Therapeutic Considerations. W. L. Bruetsch. Circulation **11:** 909-913 (June) 1955 [New York].

In an attempt to elucidate the mechanism by which narrowing and occlusion of arteries occurs in arteriosclerotic softening of the brain, an extensive microscopic examination of the brains of 20 patients with cerebral arteriosclerosis (encephalomalacia) was carried out. No evidence of the occurrence of true thrombosis was observed. The prevailing wide application of the concept of thrombosis in arteriosclerotic vascular occlusion, therefore, is incorrect. As the author's microscopic study progressed, emphasis shifted from the lipid deposit to the fibroplastic part of the atherosclerotic plaque as the major factor in the obliterative sclerosis. The presence of "embryonic foci of cellular proliferation" in the plaque appears to be the source for the slow extension of the fibroblastic obliteration in the large cerebral and other vessels, such as the coronary arteries. In the small cerebral arteries, occlusion is caused by endothelial proliferation. The proliferative changes of the endothelial cells in the small cerebral vessels and the proliferation of the fibroblasts in the atherosclerotic plaques are viewed as a morbid process occurring at a time in the patient's life when various cell types show great propensities for abnormal growth. The use of drugs that inhibit cell division and others that delay connective tissue formation may be advantageous in the retardation of the arteriosclerotic process.

Electron Microscope Observations on Collagen Diseases. G. Lelli. Policlinico (sez. prat.) 62:627-632 (May 9) 1955 (In Italian) [Rome, Italy].

Studies by means of the electron microscope were made of collagen fibrils isolated from the sternal region of 73 patients with various conditions. The results indicated an increase of resistance on the part of the fibrils with aging. In the specimens of patients with collagen diseases, however, the resistance of the fibrils, even of those outside of the involved areas, was diminished. In the specimen of one patient with scleroderma adultorum, this decreased resistance was much more marked in the fibrils of the involved areas than in those of the areas that appeared to be healthy. On the other hand, in the specimens of patients with azotemic nephritis, uremia, and cachexia, the resistance of the fibrils was increased. In the specimen of one patient with asthmatic bronchitis receiving cortisone, the fibrils were extremely resistant and completely indifferent to the hormone. The author states that, in patients with conditions in which the collagen is per se particularly resistant, cortisone may act unfavorably by speeding up the involutional process and the course toward sclerosis.

BOOK REVIEWS

Antimicrobial Therapy in Medical Practice. By Harrison F. Flippin, M.D., F.A.C.P., Associate Professor of Clinical Microbiology, Graduate School of Medicine, University of Pennsylvania, Philadelphia, and George M. Eisenberg, D.Sc., Associate in Medicine, Graduate School of Medicine, University of Pennsylvania. Cloth. $5. Pp. 284. F. A. Davis Company, 1914-16 Cherry St., Philadelphia 3, 1955.

This monograph is written by investigators who have had wide clinical experience with antibiotic and chemotherapeutic agents. The first chapter is devoted to a general description of the mode of action, pharmacological properties, dosage, and methods of administration of the sulfonamides, the available antibiotic agents, *p*-aminosalicylic acid, isoniazid, and nitrofurantoin. The next three chapters contain discussions of combined therapy, laboratory aspects, complications encountered during antimicrobial therapy, and comments concerning the management of these complications. This is followed by a general discussion of the importance of early and accurate diagnosis of infectious diseases. The next four chapters cover in detail the antimicrobial therapy of specific infectious diseases. This is by far the strongest section of the book. The next chapter deals with the prophylactic use of antimicrobial agents, and in the final chapter the authors attempt to be prophetic. The outline of this monograph is good. It should prove useful to the general practitioner and to some students. It is not a reference book, nor does it contain much that would be of great interest to the investigator. The references that are given are said to be chosen on the basis of their importance or historical interest, but many references of exceptional importance and historical interest have not been included. Scattered throughout the monograph are quotations of statements of eminent scientists. These are pleasing but do not add greatly to the value of the publication. The book contains a number of useful tables and an appendix that lists the chemotherapeutic agents together with their trade names and therapeutic indications for their use.

Handbuch der inneren Medizin. Begründet von L. Mohr und R. Staehelin. Herausgegeben von G. v. Bergmann, W. Frey und H. Schwiegk. Band 7: Innersekretorische und Stoffwechsel-Krankheiten. Teil I: Innersekretorische Krankheiten, Fettsucht, Magersucht. Bearbeitet von F. Bahner et al. Teil II: Stoffwechsel-Krankheiten. Bearbeitet von E. Grafe et al. Fourth edition. Cloth. 360 marks; 288 marks. Pp. 1163, with 190 illustrations; 1171, with 168 illustrations. Springer-Verlag, Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, Germany, 1955.

Although this is described as the seventh volume of the rejuvenated Mohr and Staehelin system of medicine, it consists of two rather weighty tomes that will be described separately. Part 1 covers the diseases of the glands of internal secretion and also obesity and emaciation. After an introductory chapter by Prof. Arthur Jores, which discusses the historical development of our knowledge of the glands of internal secretion, there are sections discussing the diseases of each endocrine gland. Professor Jores discusses the diseases of the hypophysis, the adrenals, and the sex glands; Professor Bansi covers diseases of the thyroid; Professor Fanconi considers diseases of the parathyroid glands; and Professor Bahner describes the causes and effects of obesity and of emaciation. The volume contains a discussion by Docent Doctor Zimmerman on the chemistry and metabolism of the steroid hormones. The second part discusses the diseases of metabolism. There is a lengthy section on the diseases of carbohydrate metabolism by Prof. E. Grafe and Prof. J. Kühnau, which covers diabetes mellitus, so-called renal diabetes, spontaneous hypoglycemia, and hyperinsulinism. Professor Grafe has a special section on disorders of glycogen storage. Profs. W. Löffler and F. Koller contribute a lengthy section on gout, and Docent G. Schettler a section on lipid abnormalities. Prof. A. Vannotti discusses the porphyrin disease, and Docent Kurt Schrier covers disturbances of the protein metabolism, phosphaturia, oxaluria, and oxalosis.

The arrangement of the material varies somewhat. There is usually a descriptive definition and sometimes a historical survey. The etiological factors; the general clinical findings (often with illustrative case reports); the different types of the disease; special features; the diagnosis (including the use of technical methods); the effects on special organs; the complications; the frequency and geographical distribution; the pathological anatomy, physiology, and chemistry; and the diagnosis, prophylaxis, and treatment all receive consideration. Extensive bibliographies of each subject follow the articles, and the volume ends with author and subject indexes. The articles are clearly written and comprehensive. The books are substantially bound in blue cloth, the paper is of good quality, and the type clear and easily readable. There are many graphs and excellent photographic illustrations in black and white of patients, roentgenograms, and gross and microscopic pathological lesions. There are a few colored plates where these are necessary to bring out special features. In brief, the books are a mine of well-documented information on the subjects covered and appear to contain no serious errors of omission or commission.

Moto-Kinesthetic Speech Training. By Edna Hill Young and Sara Stinchfield. Hawk. Cloth. $5. Pp. 176, with 43 illustrations. Stanford University Press, Stanford, Calif.; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, England, 1955.

As late as 1952 there still lingered in medicine the superstition that speech defects might be caused by congenital shortness of the frenulum of the tongue and could be prevented or cured by cutting this normal structure. Only one who has actually seen an unnecessary operation of this sort on a newborn baby can fully appreciate the magnificent work of recent years whereby this misconception, with many others, has been cleared up. This book summarizes the work already done by pioneers in the field, explains the many causes of speech defects, and illustrates the methods whereby children with various handicaps can be helped to speak. Sometimes the trouble has been simply a lack of people to talk to, and sometimes it is cerebral palsy, cleft palate, or deafness. Sometimes the acquisition of even a single word is a triumph, while at other times the remedy is simple, but in many cases the effect of treatment on a child's home life and social development is immense. This book deserves praise for accurate detail, balanced consideration of available techniques, excellent illustrations, interesting case histories, a stimulating bibliography, and its index. Since speech therapists now working in our schools need the understanding and cooperation of local physicians, it is recommended that every physician who has contacts with school children make an effort to see this book.

Diseases of Infancy and Childhood. By Wilfrid Sheldon, C.V.O., M.D., F.R.C.P., Physician-Pædiatrician to Her Majesty the Queen, London. Seventh edition. Cloth. $10. Pp. 804, with 231 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 14 Gloucester Pl., Portman Sq., London, W.1, England, 1955.

In the present edition of this textbook, the author has stated that it was intended to help the undergraduate student and practicing physician but not to compete with the larger reference works. It contains only short descriptions of the subjects, and no student of pediatrics would be happy with the amount of information given. This textbook might come in handy for practitioners, since it is easy to read and to understand. It could also be used effectively in teaching nurses.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

TREATMENT FOR TAENIA SAGINATA

To the Editor:—*Please outline a treatment for taenia saginata of two years' duration in a 15-year-old boy. Atabrine produces severe nausea.*

M.D., California.

Answer.—Quinacrine hydrochloride (Atabrine) may not cause severe nausea if given with sodium bicarbonate, 1 gm. in each 250 ml. of water. If quinacrine cannot be used, either of the following methods of treatment should be effective: (1) hexylresorcinol crystals (not crystoid capsules) 1 gm. and powdered acacia 2 gm., emulsified in 40 ml. of water; or (2) oleoresin of aspidium 6 ml. (must be reasonably fresh) and powdered acacia 8 gm., emulsified in 60 ml. of water. For effective use (i. e., to obtain the head of the worm) either of these mixtures should be administered by duodenal tube. Preparation of the patient should include: a light evening meal the night before treatment, with no roughage; no alcohol; sodium sulfate 15 to 30 gm. in water as a laxative at bedtime (to remove mucus from about the head of the worm); no breakfast, except water; intubate duodenum as early as practical—check for location of bulb by suction and by fluoroscopy if practical; administer anthelmintic through tube; remove tube; after two hours give purge of 30 gm. of sodium sulfate in water; and collect all intestine discharges carefully after anthelmintic until worm is passed. Search for head in later discharges if it is not found with main portion of worm.

LYMPHEDEMA FOLLOWING MASTECTOMY

To the Editor:—*Is there any new treatment for surgical lymphedema following radical mastectomy? A patient was 40 years old and had a scirrhous carcinoma of the left breast with metastasis to neighboring lymph nodes. The mass in the breast itself was centrally located. The lymphedema seems to be somewhat progressive, and I have been unable to demonstrate any new metastasis in the axilla.*

S. W. Scorse, M.D., Joplin, Mo.

Answer.—There is really no new approach to postoperative lymphedema of the arm. There is always the probability that it represents recurrent or persistent disease in the axilla. In this event x-ray therapy would be indicated. Elevation of the arm at night with overhead traction apparatus along with compression dressings on the arm usually reduces the size considerably. The compression dressings should be worn during the day as much as possible, and reelevation of the arm at intervals during the day also helps. When the lymphedema is extreme and there is no evidence of recurrent disease, the skin of the arm can be removed in long strips with an electrodermatome, the subcutaneous tissue excised down to fascia and the skin reapplied as grafts. While this procedure is disfiguring, it will reduce the discomfort and disability in the arm greatly.

INHALATION OF ZINC STEARATE POWDER

To the Editor:—*What are the hazards to rubber industry workers from the inhalation of zinc stearate powder or contact of this powder with the skin?*

Sherman L. Watson, M.D., Meadville, Pa.

Answer.—Apparently the question as to the desirability of substituting zinc stearate in the place of soapstone or talc in the rubber industry first arose about 1931 (*J. A. M. A.* 96:1818 [May 23] 1931). Some 131 instances of zinc stearate poisoning in infants were investigated by the American Medical Association committee that reported in The Journal (84:750 [March 7] 1925). This report indicated the occurrence of bronchitis and bronchial pneumonia, attributed to the combined and chemical action of zinc stearate, with a 21% mortality. It is presumable that in some instances, gross quantities of zinc stearate were involved through such accidents as the removal of the zinc stearate lid. Zinc stearate now is little used as a baby powder. Few cases are known in industry, but from Finland Drs. Norro and Uotila reported a fatality in a rubber plant worker after 29 years of employment and gave a general presentation of the harmful properties of zinc stearate in industry. Still the possibility exists that if high concentrations of zinc stearate dust arise in industry, pneumonitis could arise. Otherwise this dust is conducive to low-grade inflammation along the respiratory tract. If the use of zinc stearate in the rubber industry for dusting stock is highly desirable, this can be carried out through mechanical devices in the presence of exhaust systems so as to eliminate any substantial exposure for workmen. Dermatitis from zinc stearate is not expected.

LOOSE CARTILAGE IN KNEE JOINT

To the Editor:—*What is the accepted surgical treatment today for loose cartilage in the knee joint?*

Frank E. Wilson, M.D., New London, Conn.

Answer.—The best surgical treatment is to make an incision adequate to expose the injured meniscus. This can be an oblique incision over the articular space starting medially or laterally to the quadriceps tendon. In this way there is no muscular injury, and with retraction, the inner surface of the joint can be seen, particularly when the knee is flexed. By rotating the leg, one can see the cruciate ligaments; only the posterior horn of the medial meniscus is not visible. If it is essential to see the posterior part, a second incision may be made posterior to the collateral ligament. If there is any doubt, the entire meniscus should be removed. Occasionally, the lesion is evident, and it is apparent that it would explain all the symptoms. In this case, only the injured section need be excised.

ABDOMINAL SYMPTOMS IN DIABETES

To the Editor:—*A very obese woman with unsuspected and untreated diabetes had what appeared to be acute appendicitis. The fasting blood sugar level was 210 mg. Study of the urine showed 4+ sugar, a trace of acetone, and 4+ albumin. The history and physical findings were typical of acute appendicitis with a blood count of 18,000 white blood cells per cubic millimeter, 82% polymorphonuclear cells with 15 stabs. After medical consultation, an operation was performed. When the peritoneal cavity was opened, moderate amount of turbid fluid escaped, and the rest was aspirated and a culture taken (no growth after 72 hours). The peritoneum appeared congested. The appendix was small and trophic with some periappendicitis reaction. There was much edema of the cecum, and retroperitoneal tissues including perinephric edema. Could these physical manifestations and pathological findings be accounted for by her untreated diabetic state? Her blood on standing showed a serum that was grossly almost pure white, due no doubt to a high lipid content. The patient's postoperative condition is good. Could I have a discussion of diabetes simulating a surgical abdomen?*

M.D., California.

Answer.—This obese woman had diabetes because she showed glycosuria and hyperglycemia. Lacking knowledge about the diacetic acid and the presence or absence of showers of casts in the urine, the percentage of carbon dioxide, nonprotein nitrogen, and cholesterol in the blood, as well as the body temperature, it is difficult to decide whether the degree of acidosis was sufficient to account for the notable amount of

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

albumin, a blockage of excretion of diacetic acid, and the accompanying leukocytosis so common in diabetic coma. Conceivably latent diabetes in a fat woman, who had radically restricted carbohydrate for some time to reduce weight, could stimulate the condition described including the lipemia that is not present in the usual case of diabetic coma. Although symptoms and signs suggested acute appendicitis, the operation did not confirm that diagnosis and the height of the leukocytosis counts is also against it. Lipid nephrosis is not accompanied by acute abdominal symptoms. The edema of the tissues at operation is not easily explained, because edema is most rare in acidosis of diabetic origin. In diabetic patients, the latency of symptoms and signs of abdominal infections particularly in the appendix and gallbladder is notorious. Repeatedly an appendix or a gallbladder can explode in the ward while the patient is under observation for an entirely unrelated disorder. In diabetic coma, abdominal symptoms are so common that in a considerable percentage of the cases, a surgical consultation is almost routine and if in doubt exploration of the abdomen carried out. A pseudoperitonitis was recognized as long ago as in Kussmaul's original description of coma. The abdominal distress, Hippocratic facies, the tense abdomen, and the leukocytosis conformed closely to appendicitis, but in Borning's case the symptoms recurred in several subsequent bouts of coma although the appendix had been removed several years before.

INFANT FEEDING

To the Editor:—*What are the advantages or disadvantages of certified milk in formulas for infant feeding and the advantages or disadvantages of the addition of carbohydrate in preparing the formula? What carbohydrate is preferred?*

M.D., New York.

Answer.—Certified milk is the cleanest and most uniform in composition of any milk. It has done a great deal in raising the standards of milk production. It is expensive, and it should be pasteurized—it is usually sold raw. In localities where the general milk supply is below standard, certified milk should be used if obtainable. If the general milk supply is of high quality certified milk is not necessary. Cow's milk contains only about 4.5% of sugar. A baby can usually take with advantage more carbohydrate than this. It usually makes little difference which sugar is used. At the present time corn syrup, which contains dextrose, dextrins, and maltose, is the most popular. Starch, in the form of cereal, can be added at the third month.

TINEA CAPITIS

To the Editor:—*In this area, I have been confronted with the question of whether it is permissible to allow children infected with tinea capitis to bathe in public swimming pools. I have advocated the use of a swimming cap, but I wonder if such a restriction is adequate or unnecessary.*

William Snyder, M.D., San Antonio, Texas.

Answer.—The better course would be not to permit an infected child to use a public swimming pool. Even though the chance of transmitting the infection in a swimming pool is remote, it is still theoretically possible, and a tightly fitting swimming cap, though it would be helpful, would not be certain to give complete protection.

HIGH BLOOD CHOLESTEROL

To the Editor:—*Has any effective means been found for lowering high level of blood cholesterol in individuals presenting significant changes associated with arteriosclerosis?*

M.D., California.

Answer.—High plasma cholesterol levels can be lowered more or less effectively by (1) a low fat, low cholesterol diet containing not more than 60 gm. of fat per day or (2) the addition of plant sterols to a normal diet. The use of these procedures is still in the experimental stage, as far as long-term therapy in man is concerned. Preliminary reports are favorable but use should be deferred until the evidence is confirmed on long-term trials.

ULTRASONIC THERAPY

To the Editor:—*Is there any danger in ultrasonic treatmen*
tissue that has been treated to tolerance with x-ray
radium? *J. E. Gardner, M.D., Corpus Christi, Texa*

Answer.—There have been reports in the medical litera
on the combined use of ultrasonic and x-ray therapy for
treatment of dermatological conditions. There is as yet, howe
no clear cut evidence to show that their combined use has
particular advantage over the use of x-ray therapy alone w
it is indicated or ultrasonic therapy alone in the conditions
which it is useful. Ultrasound is primarily useful for the relie
pain and tenderness in certain inflammatory affliction of con
tive tissues, such as seen in osteoarthritis, humeroscapular
arthritis, bursitis, and some cases of rheumatoid arthritis. U
sound on the other hand is contraindicated in the presenc
malignancy, whereas x-ray therapy may be the treatmen
choice. Since the application of ultrasound is contraindic
in the presence of malignancy, it should not be used in conj
tion with x-ray therapy applied for the treatment of carcin
The real value of its combined use with x-ray therapy for
dermatological lesions has not been established.

IODIZED SALT AND TUBERCULOSIS

To the Editor:—*Does the small amount of potassium io*
ingested by adding iodized salt to the food really aggra
tuberculosis? I read that p-*aminosalicylic acid has a go*
genic effect on some patients. Would not iodized salt
tagonize this goitrogenic action? Does not the food in ce
areas contain as much or more potassium iodide than
iodized salt (1:100,000)?

Walter Weinberger, M.D., Cresson,

Answer.—The minute amount of potassium iodide that
be ingested through the use of iodized salt is of no signific
in human tuberculosis. Indeed, a distinguished group of ph
ologists recently expressed the opinion that no good evid
existed for a deleterious effect on tuberculosis even from
stantial doses of iodide. The goitrogenic action of *p*-am
salicylic acid cannot be reliably prevented by iodide. Desic
thyroid, 30 to 60 mg. per day after meals, should effect
prevent the development of goiter from *p*-aminosalicylic
The iodine content for food, of course, varies greatly wi
place of origin. In general, in nongoitrous areas, common
contain at least 10 to 100 mcg. of iodine per kilogram o
weight. A normal diet, therefore, should provide as muc
more iodide than that supplied by iodized salt, which con
10 mcg. of iodide per gram of salt.

HEMOLYTIC DISEASE OF THE NEWBORN INFA

To the Editor:—*Having once had an erythroblastotic i*
due to **A-B-O** *incompatibility, what are a mother's chanc*
having a similarly affected infant in subsequent pregnan
Does this disease follow a pattern similar to Rh incom
bility in that later infants are more severely affected?

Andrew F. Turano, M.D., Middletown, Con

Answer.—Less than 10% of all severe cases of hemo
disease of the newborn infant are caused by incompatibili
the **A-B-O** factors. A large proportion of these cases occ
primipara. There may be no increase in severity with subseq
pregnancies, and there is a good chance of these children b
normal. It is difficult to predict the disease in the expected i
from either the variety or titer of antibodies in mother's se

BLOOD TYPES

To the Editor:—*Please tell me what type of blood is re*
mended for group AB recipients when group AB bloo
not available? *Sam D. Cummins, M.D., Shreveport, L*

Answer.—It is estimated that the serums of 3% of g
A_1B individuals contain anti-O and that anti-A_1 is presen
25 to 30% of group A_2B serums. This constitutes a theore
argument for giving blood of group B to the AB recipient w
type specific blood is not available. However, experience
shown that low titer group O blood is satisfactory. Grou
blood is the third choice.

MEDICAL SCHOOL DEPARTMENT OF GENERAL PRACTICE

Robert A. Davison, M.D., Memphis, Tenn.

The general practice department of the University of Tennessee was developed on the premise that medical schools should give students some actual orientation and experience in the various forms of medical practice. The teaching of all the specialties has been traditional, but general practice, which is the most widely practiced of all fields of medicine, has been totally neglected. The established specialty clinics and medical services within the schools and teaching hospitals are highly departmentalized and in nowise resemble the conditions found in general practice. Further, in years past, the faculty of medical schools had, to a large extent, conducted general practices before specializing, but today practically none have had any experience with this form of medical care. Recognizing this, many medical schools have critically evaluated their curriculums with the purpose of offering some form of orientation and experience in general practice to the student. The specialty departments have developed and grown with the historical growth of the medical school, but there has been no such precedent set for the organization of a department of general practice. This has offered some problems in their establishment and the curricular position they should fill. The resulting curricular changes have included such teaching approaches as preceptorships, family care programs of varying nature and duration, general practice lectures, and general practice clinics.

At the University of Tennessee a large number of our students are interested in going into general practice, and we feel that this interest should be maintained and encouraged. Much too frequently the student enters medical school "social-minded and leaves lesion-minded." He is taught "how to attack a disease but not how to approach a patient." He examines a white female, age 30, gravida 3, para 3, rather than a 30-year-old white mother of three children. He enters medical school with the humanistic desire to treat people and alleviate suffering. He has never thought of patients as other than individuals in a family setting. Yet upon entering school he is soon taught to fractionate this "indivisible individual" into systems of anatomy and physiology, biochemistry and pathology. The patient soon loses her identity in the mind of the student and becomes a complicated and intricate assembly of organs and systems. To say to the new medical school applicant, "We must consider the patient as an individual with a family and social and economic environment" would seem to him a ridiculous stress of the obvious. But by the time he is a senior student he has been so thoroughly "brainwashed" that to consider the patient as other than a fleshy container for pathology too often seems unscientific and inappropriately idealistic. This we now recognize as a glaring danger in our teaching methods. Medical schools have been training medical scientists and biologists rather than doctors. The medical school should be a professional school as well as a technical school.

TEACHING THE FAMILY DOCTOR'S APPROACH

The student must be taught the humanities as well as the science of medicine. He must have firsthand experience in observing and evaluating the home and social environment in which disease finds its initial expression. The modern concept of preventive and curative medicine includes all phases of health and disease. To understand the total illness of a patient one must be familar with the socioeconomic environment in which it found its origin.[1] The family doctor's approach to sickness has been traditionally characterized by including all these factors, well leavened with understanding, compassion, and properly directed sympathy.

Recent trends in teaching at the undergraduate level express an interest in orienting students to the family doctor's approach to illness. Approximately two-thirds of our medical schools have developed preceptorships, general practice clinics, family care programs, and/or lectures on general medical problems oriented to the total medical care situation in an effort to widen the therapeutic perspective of the student. This is a result of a more total concept of illness being recognized by the faculty councils of our medical schools. The basic approach to practice as exemplified by the general practitioner as a family physician is being accepted as a sound and needed therapeutic approach long overdue in its curricular recognition. The family doctor

Read before the Section on General Practice at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 7, 1955.

[1] Packer, H.: Family Care Programs in Medical Education, South. M. J. 47: 689-695 (July) 1954.

is not to be considered as a special type of medical sociologist who functions as a diagnostic agent for treatment centers elsewhere. He differs admirably and essentially from the almost strictly hospital and office specialist by his family orientation to illness. This difference has always been his birthright. It must be fully recognized that he is also a medical scientist qualified to completely manage 85% of the illnesses to which the public is liable, and the student must be encouraged and trained to properly fill this vital place in American medicine.

GENERAL PRACTICE CLINIC

In September, 1951,[2] the faculty council of the University of Tennessee approved the addition of a general practice clinic to the outpatient teaching curriculum. The attendance at this clinic, which is held during the last two quarters of the senior year, is required of all students. It was physically set up in the outpatient department division and staffed entirely by general practitioners. This gave the students an opportunity to associate with family doctors at the student-faculty teaching level and to observe their approach to patients. The student interested in going into general practice had for the first time a faculty advisor who was familiar with this field of medicine and who could broaden his knowledge and understanding of family medical care.[3]

Clinic Equipment.—The clinic is organized and equipped as a complete and self-contained unit in such a manner as to resemble the diagnostic and therapeutic facilities available in a good general practitioner's office. Separate examining rooms are equipped with examining tables, stools, chairs, and writing desk, permitting the student and patient total privacy during the history and physical examination. If, during the examination, certain laboratory procedures seem indicated, the clinic also has a small laboratory staffed with a technician through which these determinations can be obtained. Determinations not routinely done in the lab, but which may be indicated in the complete evaluation of the patient, are referred to other laboratories in the hospital, much as might be done in actual practice. The student is instructed in numerous diagnostic and therapeutic procedures that lend themselves to office practice. Time is taken in the clinic to observe the student while he actually applies what he has learned in his specialty lectures and clinics. An electrocardiogram is available for diagnostic confirmation on cardiac diseases when desired. A complete x-ray and darkroom unit is in the clinic, and the students are instructed in the taking of radiographs in a manner expected in office practice. A minor surgery room is also equipped for office surgery. Here, the students themselves, under the supervision of the staff, do biopsies, suture lacerations, and perform whatever procedures might be indicated. Diagnostic procedures such as sigmoidoscopy and indirect laryngoscopy are performed by the student when indicated. A microwave diathermy machine is available for indicated cases, and the student is instructed in its proper use. Many other procedures characteristically done in the general practitioner's office are demonstrated to, and done by, the student.

Purpose of Clinic.—One of the objectives of this clinic is to orient the student toward the total problems of his patient and how they bear on the cause of his disability and his response to treatment. An effort is made to make the student patient-oriented rather than disease-oriented. A maximum of 20 patients are selected for the clinic session each day. The selection includes five medical cases, five major or minor surgical cases, five gynecologic cases, three pediatric cases, and two dermatological cases. No effort is made to select patients with purely psychosomatic problems, but a high percentage of them have such conditions as an overlay of their disability. In this manner the student sees a good cross section of the types of illnesses with which the general practitioner is daily confronted. Too, unlike the other clinics, this clinic does not let the student know in advance of clinic hours whether his patients will present pediatric, gynecologic, medical, or other problems. He must correlate his specialty training to the problem at hand and adjust it to the needs of the patient. The student is required to do a complete history and physical examination within approximately an hour on all new patients. This does not include the time required for special diagnostic studies he may wish to do. Patients are given an appointment to return to the same student for follow-up care.

FAMILY CARE PROGRAM

The teaching objective of the department of general practice—the comprehensive medical care of the patient and his family—could not be fully met through the general practice clinic. It did not offer the student the opportunity to practice medicine in the home and to observe the environmental background of his patient's illness. To offset this deficiency, a family care program was added in May, 1952.[4] This program was designed to permit the student to see, live, and practice family medicine by assigning him a family for the last 12 months of his school curriculum. Equipped medical bags are made available to him for house calls, and the general practice clinic functions as his private office from 4 to 10 p. m. daily. He makes appointments with his patients for all examinations and treatments that lend themselves to office management. If necessary, he hospitalizes his patients and follows them while they are in the hospital.

Through these arrangements the student is more than just an observer; he functions in every manner as the family physician. He makes house calls and office appointments, determines the diagnosis, and institutes treatment, all under the intentionally unobtrusive but consistently present supervision of the general practice staff. Great effort is made not to destroy or attenuate the professional doctor-patient relationship established by the student. When the patient accepts the student as his family physician, the student realistically reacts to this responsibility with an interest and enthusiasm not seen in his usual outpatient work. He becomes a private physician, keenly interested in all the factors that play a part in his family's medical problems. He becomes more than a medical scientist; he becomes a doctor, schooling himself in the art of medicine.

DOCTOR-PATIENT RELATIONSHIP

One hot day last summer student Eldridge was seeing one case of diarrhea after another in the pediatric clinic. He verbally expressed that he had seen enough diarrhea to last him for the next five years. When he got out of the clinic, a call from his "family" was waiting. The baby in the family had diarrhea. He immediately signed out a medical bag and hurried off to his house call saying, "That's my baby; I delivered it, and there's nothing going to happen to that kid." The small child in student Grogan's family had an accident and was brought into the emergency room. Student Grogan was in class at the time. The child was seen by the intern and the pediatric and orthopedic resident while its mother paced the floor. The child was admitted to the hospital, and the mother continued her restless steps. When student Grogan arrived, she was heard to comment, "Now that Dr. Grogan is going to see my baby and look after him, I can rest in peace. I'll go home and nurse the little one." The intern and residents meant nothing to her, but her family student doctor had developed a relationship that will not be soon forgotten by either. In the back row of the audience at graduation, a mother was seen holding a 6-week-old baby. Our medical-social worker recognized them as student Lunceford's family. She spoke to the woman. The woman explained, "My family doctor is graduating, and he delivered this baby, which was named Emmett Lunceford Jeans after him. When the baby gets older I want to be able to tell him that he went to Dr. Lunceford's graduation." Many such stories and instances come out of our family care program.

Once weekly, during both the 10th and 11th quarters, an informal family care conference is held, at which time the students discuss with the staff the preventive, therapeutic, and rehabilitative medical problems encountered during the course of their functions as family doctors. Smaller quarterly private conferences with a member of the staff are also held. Of course numerous "in the corridor" and "on the street" type conferences occur between the student and staff members. All the conferences and stories encouragingly demonstrate that we are accomplishing a patient-oriented attitude in the student; he is experiencing and learning medicine comparable to that which he will later practice. We feel that one of the important factors in the success of this program is allowing the student to assume supervised but full responsibility for the medical care of his family for a period of 12 months. If the student is allowed to be only an observer of the family environment, as his medical knowledge increases and the family's confidence in him enlarges, both will become frustrated because the student is not permitted to function as a truly helpful family physician. The doctor-patient relationship soon suffers to the point of not existing at all. The student becomes disinterested, and the family loses confidence in him; the whole stimulus for actively learning family medicine is lost. The situation becomes sterile of training value. This is the reason we believe the student should have the opportunity of diagnosing his patients' conditions and of treating his patients through home, office, and hospital arrangements.

FUNCTION AND VALUE

Our department of general practice, staffed entirely by general practitioners who hold university faculty appointments, is a completely autonomous department within the medical school, and credit for all courses offered by the department is required for graduation. The department's function is to supplement, not replace, the specialty teachings. Its value is in correlating and integrating the specialty training of the student in the overall care of the patient. The student comes to recognize the qualified general practitioner as a member of the profession, respected by his medical school as one qualified to teach and hold faculty appointments along with his specialist colleagues. He begins to view general practice as another field of medicine, honorable and worthy enough for his selection. He comes to know the background of disease through observing his patients for a full year in their natural environment. He is given an opportunity to correlate his technical knowledge of medicine with the natural setting of illness and to evaluate emotional problems of both children and adults from the vantage point of the family surroundings, which he comes to know well. He learns through experience the many factors that produce disease and retard healing.

874 Union Ave. (3).

Control of Eclampsia.—Toxemia of pregnancy has now displaced sepsis as the first cause of maternal mortality, and its severity is in some way linked with malnutrition, some of the worst cases occurring in those who are very undernourished; but other matters need consideration as well. The remarkable work reported by Hamlin (1952), from Australia, showing that eclampsia is largely a preventable disease, was partly the result of a most careful control of diet and weight gain in pregnancy; a low-carbohydrate and low-salt diet with a high protein and high vitamin content was an important aspect of the measures that were so successfully taken in Sydney to control this very serious disease. This was important work which showed the benefit that could result from close dietetic supervision of the pregnant woman. It is my view that we do not pay nearly enough attention to weight gain in pregnancy. A gain of 30 lb. (13.5 kg.) in the nine months should be the top limit of normal, and in many cases this figure should be substantially less—very much less if the patient is overweight. Some patients, indeed, should not gain any weight during pregnancy, and for these some reducing diet with sufficient of the essential food factors for the mother and her fetus may be required. Obesity in pregnancy is common enough and not without its dangers, especially if any active obstetrical or other treatment is required. Such patients may be very difficult to examine and, as a result, such conditions as mal-presentations, fetal abnormalities, pelvic tumors and contracted pelvis may be overlooked; the acute abdomen is more difficult to diagnose, anesthesia is more hazardous, and the operation and postoperative care more complicated. For over-weight patients a reduction in calorie intake, mostly by a reduction in carbohydrates, is indicated.—C. S. Russell, M.D., Diet in Pregnancy, *The Practitioner,* July, 1955.

STUDIES OF Rh SENSITIVITY AFTER REPEATED INJECTIONS OF SALK VACCINE

Neva M. Abelson, M.D., Robert M. McAllister, M.D., Arthur Greene, D.Sc.
and
Lewis L. Coriell, M.D., Philadelphia

In the last two years many physicians have been concerned that the repeated injection of Salk vaccine prepared from virus grown in monkey kidney tissue might sensitize the recipient to Rh antigens. Concern has been mainly for the Rh-negative girl who might become sensitized to the **D** factor, which is the most potent of the Rh antigens, but the question of possible sensitization of Rh-positive individuals to other blood factors also can be raised. Wiener[1] has stated that such sensitization could not occur because the Rh antigens in the monkey are slightly different from those in man. This reassurance has not satisfied the majority of physicians, and indeed it need not, for the question is subject to experimental study. Francis and associates[2] quote two investigators who found no Rh antibodies in 32 Rh-negative children (Milzer) and 2 Rh-negative laboratory workers (Frisch) who received poliomyelitis vaccine prepared from virus grown in monkey kidney tissue. This report also is not completely reassuring because injection of Rh antigen does not always evoke an immediate antibody response, though it may later promote erythroblastosis fetalis during a pregnancy with an Rh-positive fetus. The most sensitive method of measuring Rh antigenicity is to inject the material into an individual already known to be isoimmunized and to measure the subsequent antibody response. It is the purpose of this article to report a detailed study of the Rh antigenicity of Salk vaccine.

MATERIALS AND METHODS

The Rh antibody determinations were done by the saline-albumin, trypsinated red blood cell, and Coombs techniques. After the trypsinated red blood cell tests and Coombs tests were completed, albumin was added to determine if any of the reactions would be enhanced by the presence of a protein diluent. All titrations in any one series were carried out by the same technician and read by a second technician. All technicians working on this portion of the project had had at least five years' experience in the blood-grouping laboratory of the Philadelphia Serum Exchange, and their work was known to be reproducible within at least a twofold dilution. Multiple pipettes were used in making serum dilutions. Anti-**D** titers were checked against standards supplied to manufacturers of Rh typing serums by the Division of Biologics Standards of the Department of Health, Education, and Welfare, National Institutes of Health. The titers reported are those obtained with the indirect Coombs method, with the exception of the anti-**E** titers. In this case, the end-points obtained by the Coombs technique were not so clear-cut as the results in saline solution, and the latter are therefore reported. Poliomyelitis neutralizing antibodies were determined in stationary, slanted trypsinated monkey kidney tubes using 100 tissue culture doses of strains of Mahoney, MEF-1, and Saukett.

Field Trial Specimens.—The paired serums of 100 Morris County, New Jersey, children were tested for the presence of Rh antibodies. These children had received, in the spring of 1954, two injections of 1 ml. each of Salk vaccine (lot 506) at 0 and 7 days, followed by a 1 ml. injection of lot 307 vaccine at 35 days. The paired serums tested were the one drawn before vaccination and the one drawn one week after the third injection of vaccine. None of these children showed any Rh antibodies or Hr antibodies in the prevaccination and postvaccination serums. However, as already stated, such examinations do not provide adequate proof of the safety of the vaccine insofar as Rh antigenicity is concerned.

Antigens in Monkey Red Blood Cells.—In production of Salk vaccine, Macaca mulatta (rhesus) and Macaca irus (cynomolgus) monkeys are used interchangeably, because the kidney epithelial cells from both species grow in tissue culture and support the growth of poliomyelitis viruses equally well. Pooled, absorbed human blood serums prepared commercially for blood grouping and Rh testing were found to react selectively with certain of these monkey red blood cells, as shown in table 1. The erythrocytes of 77 animals received from Okatie Farms in the spring of 1954 were tested with different lots of human anti-**A**, anti-**B**, anti-**C**, anti-**D**, anti-$\mathbf{D}^u$, and anti-**E** serums. Twenty-five additional animals were tested with anti-**c** and anti-**e** serums as well. As the results in table 1 indicate, there were 23 positive reactions with anti-**A** serum, 17 with anti-**C** serum, 16 with anti-**D** serum, and 21 with anti-**E** serum. There were no positive reactions with anti-**B** serum and none with anti-**c** and anti-**e** serums. If the monkey antigens were strictly comparable to human Rh factors, one would expect that at least the **E**-negative and **C**-negative cells would be positive to **c** and **e**. Moreover, many individual raw human serums will agglutinate red blood cells from rhesus and cynomolgus monkeys, regardless of blood group or Rh status. Therefore, results of such blood grouping tests as outlined above cannot be considered specific, and, although many of the blood specimens from monkeys used in vaccine production will cross react with human serums, the antigens, as Wiener[1] has stated, are different from those of man.

PLAN OF STUDY

The failure to find Rh antibodies in serums of children who have received Salk vaccine may be due to the absence of significant amounts of Rh antigen in the vaccine. On the other hand, a detectable primary response to Rh factors is not easy to evoke in man. When sensitization is done deliberately in Rh-negative males, repeated injections of blood are usually necessary before antibodies begin to appear, and occasionally an individual fails to develop antibody after many injections have been given over a period of months or even years. However, once a person is sensitized to Rh antigens, the heightened reactivity persists, as with other antigens, even after detectable circulating antibody has disappeared from the peripheral blood. In such cases, subsequent injection of Rh antigen stimulates an immediate recall of antibody. Injection of poliomyelitis vaccine into such sensitized individuals would be a more delicate method of detecting small traces of Rh antigens than trying to detect a primary response.

TABLE 1.—*Reactions of Macaca Monkey Red Blood Cells with Human Antiserums*

Monkey Species	No.	Antiserum A	B	C	D	D^u *	E	c †	e †
Cynomolgus	35	8	0	0	2	0	0	0	0
Rhesus	67	15	0	17	14	0	19	0	0
Total	102	23	0	17	16	0	19	0	0
% positive	..	22.5	0	16.7	15.7	0	18.7	0	0

* Only D-negative specimens were tested with anti-D^u serum.
† 25 animals tested with anti-c and anti-e.

Two different groups of Rh sensitized individuals were available for study. The first group (A) was comprised of two women and six men. The women had been sensitized through blood transfusion and pregnancy and had been sterilized. The men had been sensitized through blood transfusion and subsequent injections of Rh-positive red blood cells. One of the men had had no injections of blood for four years; the remainder of the group had had injections of Rh-positive red blood cells within the preceding year. Four of the eight members of the group were sensitized to **D**; two to **C** + **D**, and one to **D** + **E**. The second group of individuals was composed of 16 men who had received repeated small injections of Rh-positive blood in 1947 to 1948. Thirteen of the 16 were known to be sensitized to Rh factors. Seven were sensitized to **D** and six to **C** + **D**. They had never received **E**-positive blood. Three of the men were not known to be Rh sensitized. These 16 individuals were divided into two further groups (B) and (C). Each group contained eight men. Of the eight men in group (B), two were sensitized to **D** and four to **C** + **D**. Of the eight men in group (C), five were sensitized to **D** and two to **C** + **D**.

Each of the three groups, (A), (B), and (C), received a different lot of Salk vaccine. Three 1 ml. intramuscular injections were given at intervals of 0, 7, and 35 days. Blood was drawn before the first dose and at regular (usually weekly) intervals for at least nine weeks. Vaccines were selected to give information on the product of three companies. The virus for lots 502 and 309 vaccine was grown at the Connaught Laboratories, Toronto, Canada, for the National Foundation for Infantile Paralysis, using a mixture of minced monkey kidney, growth medium, and virus in a Povitsky bottle that was continuously rocked on a shaking machine and harvested at the time of maximal virus yield. The formaldehyde solution N. F. (Formalin) inactivation of virus, testing, and bottling were done at Parke, Davis & Company, Detroit, in the case of lot 502 vaccine, and at Eli Lilly & Company, Indianapolis, in the case of lot 309 vaccine. The virus for lot 202 was grown and processed by the Wyeth Laboratories, Inc., Philadelphia, in bottles containing glass wool that permitted washing of the growing kidney cells three times to remove red blood cells and tissue debris before the seed virus was added to the bottles. This was the first commercially produced lot of Salk poliomyelitis vaccine. In table 2 the protein analysis of these three lots is presented. There were no significant differences among the results for the three lots.

The Rh antibody titers of group (A) before and following vaccination with lot 502 are presented in table 3. Seven of the eight individuals who received lot 502 vaccine still had detectable Rh antibody titers at the time of vaccination. After the injection of the vaccine, there was some Rh antibody rise in all of these individuals. Two showed at least a fourfold rise of anti-**C** titer, and all seven showed at least a fourfold rise to **D**^{u}. The one volunteer sensitized to **E** showed a twofold rise in anti-E titer, but this difference was within the range of technical error. The rise was most marked in the anti-**D**^{u} titers. One individual who received lot 502 vaccine (case 8) had not responded to previous attempts at Rh sensitization with whole blood, and he did not respond following the administration of poliomyelitis vaccine. After the follow-up period each of these volunteers was given a small injection of Rh-positive blood. There was no further detectable antibody response.

TABLE 2.—*Protein Assay of Poliomyelitis Vaccine, Milligram Per Milliliter*

Lot No.	Amino Nitrogen	Total Nitrogen	Nonprotein Nitrogen	Protein Nitrogen
309	0.064	0.216	0.176	0.040
502, sample 1	0.070	0.153	0.147	0.006
502, sample 2	0.070	0.155	0.143	0.009
202, type 1 *	0.058	0.151	0.113	0.038
202, type 2 *	0.065	0.166	0.115	0.051
202, type 3 *	0.065	0.159	0.113	0.046

* The results for lot 202 vaccine are presented on the three separate strain pools. The finished vaccine was made by combining equal parts of each virus type.

None of the eight volunteers who received lot 202 vaccine showed a significant rise of Rh antibody titer immediately following vaccination or in the nine-week follow-up period (table 3). One of the eight volunteers who received lot 309 vaccine had a rise of anti-C titer from 1:2 to 1:4, but this small change is not significant; neither is a change of 0 to U (undiluted) (table 3). With lots 202 and 309 vaccine, therefore, there was no evidence for the presence of Rh antigens. However, some explanation is necessary for the apparent response to lot 502 vaccine. This response might be due to the presence of Rh antigen in the vaccine, or it could be an anamnestic reaction. The latter explanation is made more likely by the fact that the group of volunteers used for testing lot 502 vaccine had been more recently sensitized than the other two groups, and most of them still had fairly high Rh antibody titers at the time they were given the poliomyelitis vaccine. As shown in table 3, these individuals developed a rise of Rh antibody only for antigens to which they already had circulating antibodies at the time the vaccine was given. The antigenicity of lot 502 vaccine was therefore retested by giving a series of three injections of this vaccine to each of the 16 volunteers who had previously been given lots 309 and 202 vaccine. Each of the 16 men received 1 ml. of lot 502 vaccine on Feb. 10, Feb. 17, and March 17, 1955. Blood was drawn for antibody determinations on Feb. 10, March 10, and March 31, 1955. All tests were negative for antibodies or only weakly positive, and there was no significant rise of antibody titer.

* Each recipient received three injections. † U = undiluted.

These tests strongly suggested that there was no Rh antigen in lot 502 vaccine and that the response previously noted was, in fact, an anamnestic reaction in volunteers who already had considerable residual circulating antibody. An alternative explanation might be that the volunteers used for lots 309 and 202 vaccine had lost their hypersensitivity by reason of the long interval since their original sensitization to Rh antigens—a period of seven or eight years (table 3). This hypothesis was put to test by selecting 5 of the 16 men at random for an injection of Rh-positive blood. On April 21 these five received intravenously 0.25 ml. of a 50% suspension of whole **DE**-positive, **C**-negative human red blood cells in acid-citrate-dextrose solution. Antibody titers two weeks later (May 5) were elevated, as shown in table 4. It is obvious that each man promptly produced a high titer of Rh antibody and thereby demonstrated the *ability to respond to a specific antigenic* stimulus. Note also the anamnestic response to **C** in the two men who had previously had anti-**C** titers. Though the blood given was **E** positive, no anti-**E** agglutinins appeared in this group, which had not previously received **E**-positive blood. Another previously sensitized man, with a residual anti-**D** titer of 1:8, was given a series of five injections of lot 502 vaccine over a six week period. His anti-**D** titer varied between 1:8 and 1:16 over this period. After a one month rest period, he was given 0.25 ml. of **D**-positive blood. His anti-**D** titers two and three weeks later were 1:128 and 1:512, respectively, showing that he, too, was capable of responding to the specific antigenic stimulus, though he did not respond to injection of lot 502 vaccine.

* U = undiluted.

Additional studies with lot 502 vaccine were designed to show whether repeated injection of the vaccine, while not capable of stimulating Rh antibody production, might still be able to alter the reactivity of the host so that he would later respond more quickly to the injection of whole blood. For this study five Rh negative volunteers who had not been previously sensitized were given 1 ml. intramuscular injections of lot 502 vaccine at weekly intervals over a period of two months. Such a procedure, using whole blood, would be expected to sensitize at least 50% of Rh-negative volunteers. No Rh antibodies appeared. After a rest period of one month, two of the five were given 0.25 ml. of whole **D**-positive blood. After a rest period of six weeks, the third man was given whole blood. A fourth volunteer was given whole blood after a rest period of eight weeks. The fifth volunteer was not available for completion of these studies. No anti-**D** agglutinins were detected in the serums of these men two to four weeks after administration of blood.

The serums of the men who were not Rh-sensitized were also tested to see if there had been any stimulation of anti-**A** or anti-**B** production. No significant change was found. Comparative titrations were also done to determine if there had been any alteration in reactivity to monkey red blood cells. None was found. Most of the numerous serum samples from these volunteers have been tested for poliomyelitis neutralizing antibodies against types 1, 2, and 3. The results are of some interest in evaluating the apparent anamnestic responses and may be summarized briefly. All lots tested stimulated the production of poliomyelitis antibodies. Lot 502 vaccine was weakest, followed in order of increasing potency by lots 506, 307, 202, and 309.

COMMENT

Some of the vaccines used in these experiments were made by procedures that permitted incubation of monkey kidney fragments and red blood cells at 36 C (96.8 F), with agitation, for over one week. Since the exact nature of the Rh antigen has not yet been determined, it could be postulated that some of these cells might disintegrate and release their antigens into the liquid phase, pass through subsequent filtration, and appear in the final vaccine. Since the exhaustive tests described here failed to disclose Rh antigenicity in the vaccines made and processed by varying techniques, one can assume that they are either removed by the processing or that they are so unrelated to human Rh antigens as to be inconsequential, as Wiener originally stated. In fact, the studies suggest that both assumptions may be correct. At any rate, it seems probable that there is no danger of Rh sensitization of man by the Salk vaccine.

SUMMARY

A certain number of blood specimens from monkeys used in production of Salk poliomyelitis vaccine cross react with serums of human origin. These cross reactions, while not typical of human red blood cells, suggest the possibility of Rh antigenicity of the Salk vaccine. Therefore, the vaccine was subjected to detailed investigation with the following results. 1. The paired specimens of 100 children inoculated in the field trials with two different production lots of poliomyelitis vaccine contained no Rh antibodies. 2. Three production lots of Salk vaccine were injected into previously sensitized Rh-negative volunteers who had little or no residual circulating Rh antibody. No significant antibody response was observed. The hypersensitivity of these volunteers was later demonstrated by injection of whole Rh positive blood. 3. Rh negative nonsensitized volunteers received many injections of one vaccine lot followed by whole blood after a rest period. No sensitization by the vaccine was demonstrated. The tests used for this study are the most sensitive tests for the presence of Rh antigens that can be devised or imagined in the present state of knowledge, and they do not show even a trace of Rh antigens in the lots of Salk vaccine tested.

VACCINATION-INDUCED POLIOMYELITIS IN IDAHO

PRELIMINARY REPORT OF EXPERIENCE WITH SALK POLIOMYELITIS VACCINE

Lawrence J. Peterson, M.S.P.H., Woodrow W. Benson, M.P.H.
and
Frederick O. Graeber, M.D., Boise, Idaho

This report is intended to present evidence confirming the presence of live virus in the poliomyelitis vaccine made available by the National Foundation for Infantile Paralysis for the inoculation of first and second grade school children in Idaho in the spring of 1955 and to present in a factual manner the impact that the use of such a vaccine has had on the state. The Francis report was accepted in Idaho as sufficient evidence that the Salk poliomyelitis vaccine was safe and potent. The vaccination program began in Idaho on April 19 and was discontinued on April 27. During that period approximately 32,000 first and second grade children received one injection of vaccine produced by Cutter Laboratories. Two lots of vaccine were used, E6058 and E6039.

Two cases of poliomyelitis were reported in Idaho on April 26, one resulting in a fatality. It was thought, of course, that some of the vaccinated children by chance alone would be developing poliomyelitis during the vaccination period, and these two cases at first were believed to be coincidental. On the morning of April 27, a report was received that in California cases of poliomyelitis were occurring in children who had received an injection of the vaccine, and later in the day information was received that the Cutter Laboratories had been asked by the United States Public Health Service to recall all of its poliomyelitis vaccine. Subsequent evidence has indicated that the vaccine that was used in Idaho contained live poliomyelitis virus. Some of the evidence in support of this viewpoint is presented in the following sections.

From the Idaho State Board of Health, Division of Public Health.

INCIDENCE OF CASES

Cases in Vaccinated Persons.—Within 26 days after the beginning of vaccination, 20 vaccinated children had developed clinical poliomyelitis, for an attack rate of about 1 to 1,600 injections. The average period of time between inoculation and clinical symptoms was 11.3 days, with a range from 5 to 26 days. Three of these children died, for a case fatality rate of 15%. Of the 20 patients, 11 showed paralysis in the arm of injection. Generally speaking, these 20 children had upper body paralysis, as compared to the usual predominance of lower body paralysis expected in this disease. The clinical impression of the examining physicians was that these 20 children were more severely involved than would be expected in an ordinary outbreak of the disease.

Objections were raised at first that, if all or almost all of the vaccine contained living virus, many more than 20 of the 32,000 children should have developed clinical poliomyelitis. This lack of an explosive outbreak is best explained on the basis of the unnatural method of infection by intramuscular injection.[1] A similar incidence of infection was observed by Kolmer in 1935 after the use of his live virus vaccine. Two other vaccinated children have developed clinical poliomyelitis. In these two cases the time elapsing between inoculation and clinical symptoms was 47 days and 90 days respectively. Because of the long interval between inoculation and illness, it is believed that these two children did not acquire poliomyelitis directly as a result of the vaccination. The only basis for this belief is the meager information available from monkey experiments. Monkeys inoculated intramuscularly with live Mahoney strain virus have an incubation period from 6 to 25 days.[2] It is possible that these two children developed no antibodies from the vaccine that they received. Table 1 gives some of the pertinent data concerning these 22 cases that occurred after vaccination.

TABLE 1.—*Children Developing Poliomyelitis After Vaccination, Idaho, 1955*

22	F	8	4/22	6/7	Stiff neck and back

Cases Resulting from Familial Contact.—On May 12, the first case resulting from familial contact was reported and, as further cases developed, it became apparent that persons outside of the immediate family were contracting poliomyelitis as a result of contact with vaccinated children. By June 14, excluding cases in vaccinated persons, there had been 53 cases of poliomyelitis reported with onset occurring after the cessation of the vaccination program. In these 53 cases, 45 persons had well-established close contact with vaccinated children. Table 2 illustrates this relationship.

TABLE 2.—*Poliomyelitis Cases Showing Association with Vaccinated Children, Idaho, 1955*

Case	Sex	Age	Date Contact Vaccinated	Onset of Illness	Contact

LABORATORY FINDINGS

Virus Isolation (Human).—Poliomyelitis virus has been isolated from the throat and stool specimens from 181 individuals. Only type 1 virus has been found. Virus has been isolated from vaccinated children who developed the disease, from vaccinated children who did not develop the disease but had a minor illness shortly after inoculation, from vaccinated children who showed no overt effects, from family contacts of children in all three of these categories, and from individuals who apparently had not been exposed to a vaccinated child nor to an individual given a diagnosis of poliomyelitis. It might be assumed that, if the outbreak of poliomyelitis hat occurred was of natural origin, an occasional type 2 or type 3 virus should be found.

* Aged 6, 7, 8, and 9.

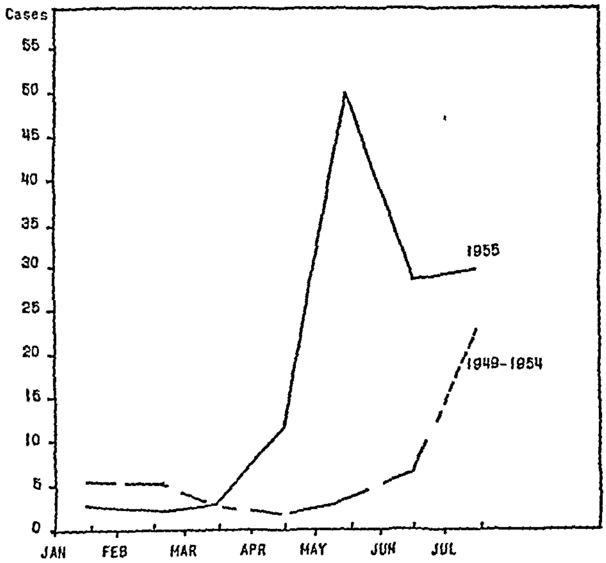
Virus Isolation (Animal).—On June 1, it was reported that Dr. Louis P. Gebhardt at the University of Utah Medical School had been successful in producing clinical poliomyelitis in a monkey injected with vaccine from lot number E6058. On June 15, Dr. Carl Eklund at the United States Public Health Service Laboratory in Hamilton, Mont., reported the isolation of type 1 virus from monkeys injected with the vaccine. Monkeys inoculated with vaccine from lot E6058 and lot E6039 developed clinical poliomyelitis. When autopsy was done, these monkeys showed typical microscopic evidence of poliomyelitis. Spinal cord emulsion produced growth on tissue culture in seven days, and type 1 virus was isolated from these cultures.

Virus Isolation (Tissue Culture).—On July 7, Dr. Eklund reported that tissue culture study of lot E6058 showed necrosis in 1 out of 50 test bottles used (500 cc. of vaccine was tested) and that this positive bottle showed type 3 virus. The isolation of type 3 virus was unexpected because all of the previous isolations, without exception, were type 1. The only apparent explanation of this phenomenon is that type 1 virus, because of superior growth qualities, masked the presence of type 3 virus. Frozen stool specimens obtained early in the study and additional vaccine are being restudied to see whether type 2 or type 3 virus can also be isolated.

Antibody Response.—A study of antibody response to the one injection of vaccine in a representative sample of the children receiving the vaccine has indicated that very high levels of antibody were obtained. In 160 consecutive blood specimens thus far analyzed from samples drawn approximately six weeks after inoculation in the Bannock County–Bingham County area, 78.8% of the children showed neutralizing antibodies to type 1, 86.8% to type 2, and 71.2% to type 3. Of the 160 children, 127 had an antibody titer of 1:1024 to one of the three types, 54 had an antibody titer of 1:1024 to two of the three types, and 8 children had an antibody titer of 1:1024 against all three types. Nine children showed no neutralizing antibody readings to any of the three types. The 1:1024 dilutions will later be run out to their endpoint. In table 3 there is given a summarization of the antibody status of the 160 children. The fact that these children have developed high antibody titers against all three types is additional evidence that the vaccine used in Idaho contained living type 1 and 3 virus and, in all probability, also contained live type 2 virus. The antibody response in these children who received one inoculation far exceeds the level reached in Idaho children in the field trial vaccine program of 1954, after three inoculations over a five week period.

IMPACT ON THE STATE

The first result of the vaccination program was the occurrence by May 14 of 20 cases among vaccinated children. In the past six years a total of only 16 cases of poliomyelitis had been reported through the end of May in children aged 6, 7, and 8. The greatest number occurring in any one of these years was four cases. The second effect was the occurrence of an unusually high incidence of cases in all age groups prior to the usual poliomyelitis season. From Jan. 1 to July 1, 100 cases of poliomyelitis were reported. In the six years from 1949 to 1954, there had been an average of 27.2 cases reported by the first of July. Two of these years, 1949 and 1952, were years of unusually high incidence of the disease. The year of highest incidence during this period was in 1949 when 48 cases occurred. The graph shown in the figure, comparing the number of cases by month this year with an average for the past six years, illustrates this difference in time of seasonal occurrence. The third observation was the fact that, whereas, in previous years the poliomyelitis occurring in the state has usually seemed to start in one of the trading areas and has then moved around the state in a somewhat haphaz-



Average number of poliomyelitis cases reported in Idaho for the first part of 1949-1954 compared to 1955.

ard manner, this year poliomyelitis cases have occurred almost simultaneously and uniformly over the entire state. There has been no area in the state that has had a disproportionate share of cases, if population density is considered.

CONCLUSIONS

Poliomyelitis vaccine used in a mass inoculation program in Idaho in 1955 contained live virus. The first result of the use of such a vaccine was to cause a wave of cases in vaccinated children. The second result the occurrence of a wave of cases in the contacts of cinated children. The widespread isolation of polion litis virus and the uniform distribution of cases indi that the state has been heavily seeded with virus p to the normal poliomyelitis season. The effect of early, unnatural seeding is unpredictable. (The number of cases as of Aug. 1 was 130.)

700 Jefferson St. (Dr. Peterson).

PERINATAL MORTALITY

Edwin M. Gold, M.D., Brooklyn, N. Y.

Perinatal mortality is a relatively new term. In 1948, Peller [1] felt that there was such a close association between fetal death ratios and neonatal mortality rates that he suggested their combination into a "perinatal mortality rate." Baumgartner and Erhardt [2] have reiterated the validity of this concept. The World Health Organization Expert Committee on Health Statistics in 1950 [3] recommended that the fetal death and neonatal mortality statistics be published alongside of each other so that they could be considered as a unit. Davis, Potter, and Bruce [4] referred to perinatal mortality as an inclusive term to include stillbirth and neonatal mortality. Obstetricians should think of perinatal mortality as expressing loss of life just before, during, or just after birth, since these are areas of prime obstetric responsibility. Therefore, in New York City a perinatal mortality rate is obtained by the following formula:

$$\frac{\text{Infant deaths (under 1 week) plus fetal deaths (28 weeks and over)}}{\text{Live births plus fetal deaths (28 weeks and over)}} \times 1{,}000$$

This formula reveals perinatal mortality to be composed of infant deaths (under one week) and late deaths (over 28 weeks' gestation). The vital stati of New York City for the years 1946 through 1 (table 1) indicate a decline in the perinatal mort rate of 19.5%. The late fetal deaths (28 weeks over) declined 28.0%, and the early infant deaths der 7 days) declined 12.0%. This represents impr ment, though not as rapid improvement as is note the decline of the maternal mortality rate of 44.4% the same period.

EARLY INFANT DEATHS AND THEIR CAUSES

Since the early infant deaths declined least, (12 let us examine them first to see why. They com 90% of the infant deaths in the first month of life, over 50% of them occur on the first day of life. M noteworthy is the fact that 90% of the early in deaths are due to perinatal causes; namely, premat in 51%, birth injuries and malformations in about each, and anoxia and erythroblastosis in 11%.

Prematurity.—Prematurity, accounting for half neonatal mortality in New York City and 79.1% natal day deaths in Chicago,[5] is a formidable caus early infant deaths. The incidence of prematurit New York City during the years 1946 through 1 has remained fairly constant at a level of 8.1% o live births, with an incidence of 7.5% in the whit against 11.5% in the nonwhite population. To red the early infant death rate further and more rapidly heretofore, prematurity must of necessity be preve and treated. The clues to reduction of prematurity sh be the relationships that have been shown [6] between parity, socioeconomic conditions of the pregnant wom and quality of prenatal care with the incidence of mature birth.

Recent confirmatory studies in New York C based on the criteria developed from birth certifi data, have pointed out that prenatal care is started (in the last trimester of pregnancy) in certain group pregnant women: the nonwhite patients in gene women under 20 and especially multiparas under patients delivered in municipal hospitals; Negro pati delivered on ward services of voluntary hospitals; patients delivered at home. All these data revea need to assure early and continuous prenatal care of pregnant women, but especially among the prio

roups mentioned. This is an area where maternal and hild health services of municipal health departments an work hand in hand with the obstetrician, the hospi-l, and other community agencies to locate such pri-rity groups of patients and assure their early and con-nuous care as one major means of reducing the inci-ence of prematurity.

Therapeutically, the most current, sound obstetric rinciples of management and care of the patient in remature labor and during premature delivery should e applied. Particular emphasis should be placed here n the conservative management of the patient with remature rupture of the membranes; she should be ospitalized and no attempt made to induce labor. lacenta previa should be treated expectantly to insure iability of the fetus. Cases of Rh and AB isoimmuniza-on should be carried to full viability before the preg-ancy is terminated. Finally, the recently summarized rinciples[8] of management of the premature labor and elivery should be continuously disseminated and tressed.

proprietary hospitals, 39.9% of the patients were delivered by midforceps, 62% by breech, 37.5% by internal podalic version, and 25% by cesarean section without a qualified obstetrician in attendance. Thus, it is timely to reiterate that each maternity service should provide a qualified chief of service and that this chief should set up and enforce consultation policies in the interest of lowering the incidence of birth injury.

Malformations.—There is not much that can be constructively stated about malformations except that their incidence remains stationary at about 1.5% of all births. About 15% of early infant deaths are directly or indirectly ascribable to this cause. The solution to the problem of lowering incidence of malformations lies in further research in the fields of environmental pathology and the influence of nutrition on the developing fetus in the first eight weeks of intrauterine life. The role of viral diseases in the first 12 weeks of gestational life in producing malformations is becoming more definite, though not particularly well understood. Prophylaxis therefore still stands in abeyance.

TABLE 1.—*Changes in Perinatal Mortality Taken from the Vital Statistics of New York City from 1946 to 1953*

	1946	1953	Percentage of Change
Live births	152,736	161,499	....
Infant deaths (under 1 yr.)	4,239	3,945	....
Infant death rate (per 1,000 live births)	27.8	24.4	(—) 12.2
Neonatal deaths (under 1 mo.)	3,279	2,945	....
Neonatal death rate (per 1,000 live births)	21.5	18.2	(—) 15.3
Early neonatal deaths (under 7 days)	2,804	2,623	....
Early neonatal death rate (per 1,000 live births)	18.4	16.2	(—) 12.0
Fetal deaths	12,980	19,357	....
Fetal death ratio (per 1,000 live births)	85.0	119.9	(+) 41.1
Fetal deaths (28 weeks and over)	2,947	2,239	....
Fetal death ratio (per 1,000 live births)	19.3	13.9	(—) 28.0
Perinatal mortality	5,751	4,862	....
Perinatal mortality rate	36.9	29.7	(—) 19.5
Maternal mortality	179	105	....
Maternal mortality rate (per 10,000 live births)	11.7	6.5	(—) 44.4

Birth Injury.—Birth injury is the second major cause of early infant mortality in New York City. The incidence of reported severe birth injury for the year 1948 in New York City was recently reported[9] as 1.7 per 1,000 live births. This study showed the relation of type of delivery to reported severe birth injury. The reported severe birth injury rates per 1,000 live births were 0.21 in spontaneous delivery and 1.3 in low forceps and cesarean section but jumped to 30.0 with version, 17.5 with high forceps, 14.4 with midforceps, and 14.0 with breech delivery. This study also pointed out that, despite recommendations of the Advisory Obstetric Committee of the New York City Health Department that consultation with a qualified obstetrician be required in all obstetric operations other than low forceps delivery, the facts showed otherwise. In the reported cases of severe birth injury occurring on the ward services of the municipal and voluntary hospitals, 60% of the midforceps and 85% of the breech deliveries were performed by the house staff without a qualified attending obstetrician in attendance. In the reported cases of severe birth injury on the private services of voluntary and

Erythroblastosis and Anoxia.—Together, erythroblastosis and anoxia account for 11% of early infant deaths in New York City. Deaths due to Rh incompatibilities and AB isoimmunization factors may be related to the thoroughness of antepartum diagnosis and the preparations in the immediate puerperium for coping with them. The anoxia cases in this group are associated with prolonged labor, operative delivery, and hemorrhagic complications at or near term, such as abruptio placenta, placenta previa, marginal sinus rupture, and other hemorrhage. Better obstetric management, more liberal use of consultation, skilled obstetric care for operative delivery, and temporizing in the management of placenta previa with liberal recourse to blood replacement as needed are contributing to reduction of early infant loss from these causes. In addition, increas-

9. Gold, E. M.; Clyman, M. J.; Wallace, H. M., and Rich, H.: Obstetric Factors in Birth Injuries with Consideration of the Value of Birth Certificate Reporting, Obst. & Gynec. 1: 431-436 (April) 1953.

ing awareness of the role the qualified anesthetist plays in bringing new conduction and regional anesthetic techniques into the delivery room and his growing role in supervision of neonatal resuscitation will further tend to decrease infant loss from anoxic causes. Adherence to such a policy is a potential in reducing anoxic complications as a major cause of early infant deaths.

Before the second component of perinatal mortality is analyzed—late fetal deaths (28 weeks and over)—it should be noted in table 1 that fetal death ratio (all fetal deaths) has risen 41.1% during the years 1946 through 1953 and the upward trend was continuous. This is ascribable to the increased reporting of early fetal deaths, particularly in the under-20-week group. The late fetal deaths (28 weeks and over) have fallen 28% during this eight year period. Numerically they represent approximately half of the perinatal deaths herein defined, the other half being the early infant deaths. This leads to a conclusion that possibly, by improvements in prenatal care and improved nutrition, together with improved techniques of coping with the complications of early pregnancy, more fetuses are now being carried beyond the 28th week and delivered alive. In other words, more "poor risk" infants are brought into the early neonatal period, thereby accounting for the relatively slower improvement of the early infant death rate, which declined only 12%.

TABLE 2.—*Reported Fetal Deaths by Cause of Death at Twenty-Eight Weeks and Over in New York City in 1952*

	No.		Percentage of Total	
All Causes	2,448		100.0

Ill-defined and unknown causes	1,017		41.6	

LATE FETAL DEATHS AND THEIR CAUSES

The late fetal deaths (over 28 weeks), the other component of our perinatal mortality, represent slightly more than 10% of the total fetal deaths per year in New York City but approximately 50% of the perinatal mortality. These are the antepartum and intrapartum intrauterine deaths.

Table 2, listing the reported fetal deaths at 28 weeks and over by cause of death for the year 1952 in New York City (the latest year of complete tabulation of la fetal deaths by cause), shows three major groups b cause.

Maternal Causes and Conditions.—Maternal cond tions represent 20.4% of the total. Of these cause toxemia represents 50%, abnormal labor 20%, an chronic diseases (such as diabetes, syphilis, and vascu lar and renal diseases) another 20%. Toxemia of pre nancy and chronic diseases of the mother represent challenge in relation to prenatal care. The same fact of implementing prenatal care, particularly in the pr ority group of mothers alluded to in discussion of ear infant deaths, is applicable here.

Causes in the Fetus, Placenta, and Cord.—Cond tions in the fetus, placenta, and cord represent 38% the late fetal deaths. Of these causes, premature separ tion of the placenta represents 29%, other placental ar cord conditions 39%, congenital malformations 18 and erythroblastosis 10%. If the high association premature separation of the placenta with toxemia, t high association of other placental conditions, such infarction, fibrosis, and degeneration with the vascul and renal complications of pregnancy, and the role antepartum casefinding and preparation in relation erythroblastosis are considered, the import of adequa antepartum care as the theoretical potential in loweri the incidence of late fetal deaths from these causes c again be recognized.

Ill-Defined or Unknown Causes.—Of paramount i terest is that in 41.6% of the late fetal deaths t cause was ill-defined or unknown. Hughes and Schoe eck[10] have stated that, if a woman had a premature d livery, stillbirth, or abortion in one pregnancy, she ha a better than average chance of difficulty in future pre nancy. On these grounds they recommended preco ceptional evaluation of prospective parents with a hi tory of previous unsatisfactory pregnancies. Such eval ation would be done in preconceptional clinics. Aaro Levine, and Gitman[11] on the basis of experiences such a clinic emphasize the need for further study of t uterine environment, the endometrium, and uteri anomalies because of the importance of these factors i repeated pregnancy wastage.

In New York City at present, the autopsy rate in la fetal and early infant deaths ranges between only 25 an 40%. In Chicago, on the other hand, autopsies are be ing performed on approximately 85% of all dead in fants.[12] Thus a vital source of information as to ana tomic cause of perinatal mortality in New York City i being sadly neglected. A pertinent recommendatio would be to increase autopsy percentages at the individ ual hospital and community level. These autopsies i both late fetal and early infant deaths should be don promptly, by specially trained pathologists, and the re sults collated with the clinical course of the mother s that the findings would be more meaningful. Anothe suggestion would be to stimulate the development o "perinatal mortality conferences" at hospital level a which the obstetrician, pediatrician, anesthetist, an pathologist could pool their knowledge during the cas study. Much information of a preventive and thera peutic nature can come from such an approach. Applying this same technique on a community level, we should stimulate the development of perinatal mortality committees patterned after the maternal mortality committees that have so materially aided in the reduction of maternal mortality in this country by eliciting the errors of omission and commission, from which the current recommendations of good obstetric practice have emanated.

CONCLUSIONS

In conclusion then, we have attempted to focus attention on the fact that perinatal mortality is composed of early infant deaths (under 7 days) and late fetal deaths (over 28 weeks), both areas where obstetric responsibility is high and the problems of which are inseparable. In order to speed up the decline in perinatal mortality, continued effort in the following areas is suggested. 1. In preconceptional care the effort should be to investigate families with a history of pregnancy wastage in the interval between pregnancy, to delve deeper into the realms of environmental pathology, and to increase research in the role that endometrial insufficiency and uterine anomalies play in pregnancy wastage. 2. In prenatal care attempts should be made to identify, locate, and give early and continuous high quality prenatal care to all pregnant women but especially to those in low socioeconomic strata, nonwhite patients in general, women under 20, and especially multiparas under 20. 3. Those concerned in intrapartum and postpartum care should disseminate and apply currently accepted standards of skilled obstetric and anesthesia care in all deliveries and especially in premature deliveries. Qualified consultation in obstetric and newborn infant practice should be used freely. An attempt should be made to raise the numbers and quality of autopsies performed at the hospital and community level to permit better evaluation if possible of causes of perinatal mortality on an anatomic basis. 4. Perinatal mortality committees should be further developed, patterned after the preexisting maternal mortality committees. Such committees should represent joint cooperation of the county medical society and the local health department.

47 Plaza St. (17).

Tuberculin Testing.—In spite of many studies of its value, many physicians still neglect the tuberculin test when the differential diagnosis of a pulmonary lesion is considered . . . [because] there seems to be a feeling that "since nearly every adult is tuberculin-positive, there is little reason to do the test." . . . Newer procedures in diagnosing lesions of the lungs are stressed . . . [and] the physician may become involved in the intricacies of the new tests rather than attempt to evaluate his patient on the basis of tried and true ones. . . . [Also] the present-day treatment for tuberculosis has become so simplified, with such a low percentage of toxic or ill effects, that the temptation is very great to start treatment before clinching the diagnosis. . . . The trend toward ambulatory care of tuberculosis hastens the feeling that treatment should be started just as soon as a pulmonary lesion is found. Nevertheless, the physician must not forget that the diagnosis of tuberculosis carries with it great social, economic, and physical responsibilities. . . . He must make the diagnosis with great certainty and caution. . . . The tuberculin test is a simple, cheap, and comparatively short test in which the possibility of a lesion being tuberculous can be ruled out. . . . It is one that has stood the test of time, and . . . it has not been supplemented by new and more intricate methods. It will become more valuable as our control of tuberculosis improves.—D. Jackson, M.D., The Value of Tuberculin Testing, *A. M. A. Archives of Internal Medicine*, June, 1955.

CLINICAL NOTES

V, A "NEW" Rh ANTIGEN, COMMON IN NEGROES, RARE IN WHITE PEOPLE

Albert DeNatale, Ph.C.
Amos Cahan, M.D.
James A. Jack, M.S., New York
Robert R. Race, Ph.D.
and
Ruth Sanger, Ph.D., London, England

A "new" blood group antibody has been found in the serum of a white, adult patient (Mr. V), in St. Luke's Hospital, who suffered from an obscure anemia and received 26 transfusions between March 18 and Sept. 15, 1954. The antibody was first discovered at St. Luke's Hospital when the cross match for the 27th transfusion was incompatible; subsequent inquiry showed that this prospective donor was a Negro, as were six of the previous donors. The red blood cell antigen identified by this antibody at first appeared to be confined to Negroes but it has now disclosed itself as being present rarely in whites, frequently in New York Negroes, and still more frequently in West Africans. The antigen is associated with the Rh system, but until its precise place in that system becomes clear we propose to call it V.

ASSOCIATION OF V WITH Rh SYSTEM

The "new" antibody, anti-V, might not have been pursued had not the panel of test cells then in use at the Knickerbocker Foundation included several samples from Negroes. In these preliminary tests the only two positive reactions were among the six Negro samples in the panel of 20 selected bloods. Attention was thus focused on Negro blood, and samples from 168 New York Negroes were then tested with anti-V; they were also tested for the A_1 A_2 BO, MNSs (including Hu, He, and Vw), P, Rh, Lutheran, Kell, Lewis, Duffy, and Kidd groups. The two categories of people, those with V and those without it, had undisturbed distributions of all these groups save Rh. The distribution of V in the Rh types of the New York Negroes, and in some West African Negroes subsequently tested, is shown in table 1; the lack of V+ lower in the list can be crystallized in the following tabulation. This is out of propor-

	Samples Representing	
	At Least One *cde* or *cDe* Chromosome	No *cde* nor *cDe* Chromosome
V+	105	0
V−	191	22

From St. Luke's Hospital (Dr. DeNatale); the Knickerbocker Foundation *(Dr. Cahan and Mr. Jack); and the Medical Research Council* Blood Group Research Unit, the Lister Institute (Drs. Race and Sanger).

Dr. Luis A. Amill, Director of the Blood and Plasma Bank, St. Luke's Hospital, New York City, gave help and advice in this study.

Dr. D. A. Cannon, Medical Research Institute, Lagos, Nigeria; Dr. J. N. Marshall Chalmers, St. George's Hospital, London, England; Dr. G. M. Edington of the Medical Research Institute, Accra, British West Africa; and Mr. I. Sackey, Accra, supplied the samples from individuals and families in West Africa.

Dr. R. A. Zeitlin, South London Transfusion Centre, and the staff of the Lister Institute, London, England, supplied most of the samples from white persons.

Dr. T. J. Greenwalt, Milwaukee Blood Center, Milwaukee, supplied samples from the Milwaukee family.

Dr. C. A. Holman, Lewisham Group Laboratory, and Dr. K. E. Saunders, Dulwich Hospital, London, England, supplied samples from the Jamaican families.

tion to the extent that the "exact" probability is 1 in 9,860. A little of the sting is taken out of this probability because so many comparisons were made (for example, V+: V— with A: not A and V+: V— with M: not M); however, as will be seen from the family evidence, the association between V and Rh detected thereby was a true one.

* Rh antiserums used were: anti-C, -c, -C^w, -D, -E, -e, -f, and sometimes, anti-C^x and anti-E^w.

† *cDe/cDe* cannot, without family evidence, be distinguished from *cDe/cde*.

‡ *CDe/cDe* cannot, without family evidence, be distinguished from *CDe/cde*.

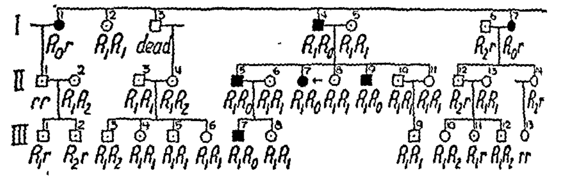
§ *cDE/cDe* cannot, without family evidence, be distinguished from *cDE/cde*.

FREQUENCIES

Table 2 shows the frequency of the antigen V, and that of its gene, in the three groups of people thus far tested. It can be estimated that in West African Negroes about 25% of *ce* chromosomes (*cDe* and *cde*) carry the gene *V*, and that in New York Negroes about 18% of these chromosomes carry it; owing to the smallness of the relevant samples it is not yet possible to give separate estimates for the two chromosomes. The West African sample, from Lagos, Nigeria, and Accra, British West Africa, is presumably heterogeneous; the people belonged to at least six different tribes. The Rh frequencies agree well with those of Chalmers, Ikin, and Mourant[1] for Nigeria. The New York Negroes were blood donors selected for darkness of skin. The Rh frequencies are very close to those found by Miller, Rosenfield, and Vogel[2] for the same population. The whites in London, England, were donors to the South London Transfusion Centre or were members of the Lister Institute. Both V+ donors and many of the relatives of one of them have been visited; there was no sign or history of any African ancestry. The blood of 444 white donors in New York has also been tested; two samples were V+, and both of them were found to be from Puerto Ricans. Three other Puerto Ricans included in this group were V–.

INHERITANCE

It proved too difficult to get samples of blood from the families of New York Negroes, so attention was turned to the possibility of getting family samples from West Africa. While the West African families (table 3) strongly suggested that the antigen V was inherited as a Mendelian dominant character, they were not capable of throwing light on the relationship of V to Rh because none of them segregated for both Rh and V. This stimulated us to continue the search for V in white peo in white families the segregation of the Rh genes is m clearer and V, if found, would inevitably be in the h erozygous state and so, with luck, should segregate The family of one of the two London V+ donors (ta 2) provided exactly the information needed. The fa heritage is shown in the figure, which gives proof that antigen is a dominant character, for if it were reces four unrelated members of this English family wo have to be carriers of the gene responsible, i. e., I-5 II-6 and the father and mother of generation I, wh is not to be entertained.



Heritage of English family, showing linkage between V and Rh. designates family members with antigen V, dot designates those who the antigen V, and arrow designates propositus. *Ro* = *cDe*, r = *cde*, *CDe*, and R_2 = *cDE*. Rh antiserums used were: anti-C, -c, -C^w, -D -e, -f, and, sometimes, anti-C^x and anti-E^w.

The family also shows linkage between V and the *V* gene is carried on *cDe* chromosome. Propos II-7 and appropriate members of her immediate fa were at first labeled *CDe/cde* (cannot be distinguis serologically from *CDe/cDe*); however, the group I-1 and her son and the groups of I-7 and her daug and granddaughter show that I-4 is evidently *CDe/c* Since in this part of the argument we are assuming linkage that we want to demonstrate, it should be poi out that the family of I-4 shows the linkage of V with irrespective of whether the chromosome with which linked is *cDe* or *cde*: this branch of the family sc 7:0 for linkage and to it can fairly be added I-2, mak the score 8:0. (The ratio represents the number people that show linkage to the number that would t have to be recombinants.) The probability that this parent linkage is due merely to chance is but 1 in 1 The family was also tested for the other eight blood gr systems and, some of the members, for the ability taste phenylthiocarbamide. The segregations were s that close linkage could be excluded between V and MNSs, P, and Kidd; the other groups did not give linkage information.

TABLE 2.—*Antigen V: Phenotype and Gene Frequencies Three Groups of People*

FURTHER STUDIES

Serologic Details.—The blood groups of Mr. V. w B, *cde/cde*, Lu (a–), K–; his P, MNSs, Lewis, Duff and Kidd groups were in doubt due to the presence

---

Dr. A. E. Mourant, Medical Research Council Blood Group Reference Laboratory, Lister Institute, London, England, supplied many of the antiserums.

1. Chalmers, J. N. M.; Ikin, E. W., and Mourant, A. E.: The ABO, MNS and Rh Blood Groups of the Nigerians, Ann. Eugenics **17**: 168, 1953.
2. Miller, E. B.; Rosenfield, R. E., and Vogel, P.: On the Incidence of Some of the New Blood Agglutinogens in Chinese and Negroes, Am. J. Phys. Anthropol. **9**: 115, 1951.

many transfused cells. The serum of the patient contained, beside anti-V, anti-Wr^a. Anti-V gives clear reactions by the indirect antiglobulin method; it also agglutinates V+ cells suspended in albumin. The agglutination of trypsinized V+ cells is powerful but somewhat obscured by weaker "false" agglutination of all trypsinized V− blood cells tested with this serum. It was obviously necessary to dissociate V from other antigens rare in white persons: V+ red blood cells failed to react with anti-C^x, -E^w, -Mi^a, -Be^a, -Vw, -Wr^a. Two examples of the rare Rh genotype *-D-/-D-* did not react with anti-V, nor did an example of the rare Rh genotype *cdeF/cdef*. It seems that the V antigens of white and Negro people must be the same: when anti-V was absorbed by V+ red blood cells from a white person it lost its reaction for V+ Negroes and vice versa. Saliva from a V+ person, as expected, did not inhibit the reaction of anti-V.

† *cDe/cDe* cannot, without family evidence, be distinguished from *cDe/cde*.
‡ *cDE/cDe* cannot, without family evidence, be distinguished from *cDE/cde*.

Development.—The antigen V is well developed at birth, judging by the cord blood sample in family 8 (table 3).

Sickling.—Blood samples of the West African Negroes were tested for sickling by Dr. Edington or by Dr. Marshall Chalmers. In the first 40 samples (in which there had been some selection for sickling) there was a highly significant association between the presence of sickling and the absence of V (p = about 1 in 1,000). This apparent association was entirely obliterated in the final counts. Perhaps the earlier sample was heterogeneous; heterogeneity was considered as a possible explanation of the association observed by Shapiro and Vandepitte[3] between Rh and sickling in the Congolese Bantu, a Negro tribe in the Belgian Congo.

TRANSFUSION AND PREGNANCY

Tens of thousands of white people must have received blood transfused from Negro donors, yet only Mr. V is known to have responded by making anti-V. It seems that V cannot be efficient at immunizing, but we must remember that the antibody would only be disclosed by a second transfusion of Negro V+ blood and furthermore, that it would be overlooked unless Negro blood were included in the subsequent investigation. The blood of the two English V+ donors was seen surviving in samples from their V− recipients two to three weeks after transfusion. One of these recipients has had a second transfusion of V+ blood without adverse reaction and without making detectable anti-V. The antigen V can hardly be an effective cause of hemolytic disease of the newborn infant; over 20% of Negro matings could provide candidates, yet the disease is relatively uncommon in these people and, when it does occur, is usually attributable to anti-D.

DIFFICULTIES IN FINDING PRECISE PLACE OF V IN Rh SYSTEM

The significantly disturbed distribution of V within the Rh groups of unrelated people and the absolute linkage of V with Rh in the family shown in the figure clearly point to V being part of Rh. Assuming that V is part of Rh then its gene can be part of some *cde* chromosomes (because some *cde/cde* people have the antigen V); the gene *V* can also be part of some *cDe* chromosomes (see figure and table 3, family 9). The evidence is strong that *V* is not usually part of *CDe* or *cDE* chromosomes (because no *CDe/CDe, CDe/cDE, or cDE/cDE* people have yet been found to have V, and this absence is highly significant). If the chromosomes *cde* and *cDe* may carry the gene *V* and if the chromosomes *CDe* and *cDE* usually do not, then we would expect to find a higher frequency of the antigen V in *cde/cde, cDe/cde,* and *cDe/cDe* people than in *CDe/cde, CDe/cDe, cDE/cde,* and *cDE/cDe* people. This expectation was not realized in the New York Negroes, and the deviation is a significant one:

---

[3] Shapiro, M., and Vandepitte, J.: Blood Groups and the Sickle Cell Trait in the Congo Bantu, Résumés des Rapports et Communications, Ve Congrès International de Transfusion Sanguine, Paris, p. 73, 1954.

	V+	V—
Genotypes involving 2 *cde* or *cDe*..........	26 (29%)	65
Genotypes involving 1 *cde* or *cDe*..........	19 (31%)	43

but it was realized in the West Africans where the fit is good:

	V+	V—
Genotypes involving 2 *cde* or *cDe*..........	43 (46%)	51
Genotypes involving 1 *cde* or *cDe*..........	17 (35%)	82

The testing of more New York Negroes may solve this puzzle.

Is is unlikely that the gene *V* is allelomorphic to *D*. For example, I-1 in the figure is of the genotype *cDeV/cdev*, and her D antigen is apparently of the usual kind. (The anti-D in use was shown to be free from anti-V by its negative reaction with *cde/cde* V+ red blood cells.) The gene *V* is probably not allelomorphic to *C* or to *E*. Blood containing V can have apparently normal C and c antigens (as, for example, *CDe/cDe*); blood containing V can also have apparently normal E and e antigens (as, for example, *cDE/cDe*). The gene *V* could be an allelomorph of *f*. It is rather striking that the chromosomes that, in Negroes, may have *V* (*cde* and *cDe*) are those that, in whites, with but few exceptions, have *f* (Rosenfield and co-workers[4]).

The Negro samples in tables 1 and 3 were tested with anti-f and, as in whites, those bloods representing the chromosomes *cde*, *cDe* or cD^ue possessed the antigen f. Of the New York Negro samples 60 were tested against titrations of anti-f: there was a faint and far from significant hint that those containing the antigen V had a little less f antigen than had those lacking V. This slight hint made us wonder whether our anti-f serum is really anti-f plus anti-V. (Anti-f was one of several antibodies produced by a white patient in New York who had received about 35 transfusions of blood, some of which may have been donated by Negroes.) We have not, by appropriate absorptions, been able to demonstrate anti-V in the anti-f serum, but this does not convincingly exclude its presence there. Had we been able to exclude this possibility of *V* being an allelomorph of *f* we would have looked on it as a representative of a fifth Rh locus—*G*. When better understood, V cannot fail to throw further light on the structure of the Rh genes: already it is of potential clinical, anthropological, and evolutionary importance.

SUMMARY

A "new" blood group antigen has been found that, for the present, is being called V. It is common in Negroes and rare in white persons. Of 150 West Africans, 60 (40%) had V; of 168 New York Negroes, 45 (27%) had V; of 407 London whites, 2 (0.5%) had V; and of 444 New York whites 2 (0.5%) had V. The antigen is inherited as a dominant Mendelian character and belongs to the Rh system. The gene *V* can be part of some *cde* chromosomes and of some *cDe* chromosomes, but its precise place in the system is not yet clear.

300 W. 43rd St. (36) (Dr. Cahan).

CHEMICAL LABORATORY

The following report is the result of additional st on caffeine in instant and decaffeinated coffee.

WALTER WOLMAN, Ph.D., *Director*

INSTANT AND DECAFFEINATED COFFEE

In the report of the Chemical Laboratory in T JOURNAL, July 23, 1955, page 1030, entitled "Xanthi Tannins, and Sodium in Coffee, Tea and Cocoa" val for the caffeine content of the coffees examined w based on a gravimetric procedure. Subsequently, it found that this method leads to erroneous values caffeine in decaffeinated coffees. Nitrogen determinati by the Kjeldahl method on the residue obtained in gravimetric procedure lead to results that more ac rately represent the actual caffeine contents of coff The results reported in table 1 were obtained by use of the Kjeldahl nitrogen method. The values pressed as maximum caffeine per cup, in milligrams, calculated on the basis that 8.0 gm. of the ground b coffee is equivalent to a rounded tablespoon and gm. of the instant coffee is equivalent to a rounded spoon. Two hundred fifty milliliters of liquid is ta to represent a cup. If 1.3% is taken as an average the caffeine content of regular roasted coffee beans, results obtained indicate that the available decaffein ground bean coffees contain roughly one-fortieth of amount of caffeine found in the regular coffee. The caffeinated instant coffees also contain about one-fort of the amount of caffeine present in regular instant fees. This is equivalent to 97% or more removal caffeine from these coffees as has been indicated by v ous advertising claims. Table 2 gives the caffeine cont of regular instant coffee determined by the Kjeldahl trogen method. The values expressed as maximum feine per cup, in milligrams, are again calculated on basis of 2.5 gm. of the regular instant coffee per 250 cup.

TABLE 1.—*Actual Amounts of Caffeine, by Kjeldahl Nitrogen Method*

	Average Caffeine, %	Maximu Caffeine per Cup, Mg.
Decaffeinated ground bean coffee		
Brand F	0.03	2.4
Brand G	0.05	4.0
Decaffeinated instant coffee		
Brand F	0.10	2.5
Brand H	0.08	2.0

TABLE 2.—*Caffeine Content of Regular Instant Coffee, by Kjeldahl Nitrogen Method*

Brand	Average Caffeine, %	Maximu Caffeine per Cup. Mg.
B	3.70	93
D	3.45	86
E	3.95	99

In the note appearing in THE JOURNAL, Aug. 13, 19 page 1369, some question was raised about the relia ity of the analytical procedure used originally. The d now presented indicate that inaccurate results were ported in the original article of July 23 in regard the caffeine content of instant and decaffeinated coffe

APPROVED INTERNSHIPS AND RESIDENCIES IN THE UNITED STATES

ANNUAL REPORT ON INTERNSHIPS AND RESIDENCIES BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Edward H. Leveroos, M.D., Arthur N. Springall, M.D. and Carl T. Heinze, M.S.H.A.

Annual Report

This 29th Annual Report of the Council on Medical Education and Hospitals presents information and statistical data on intern and resident training programs conducted in Council-approved hospitals located in the United States, Canal Zone, Hawaii, and Puerto Rico. The report is composed of descriptive material; statistical tables; information on the National Intern Matching Program, the Ad Hoc Committee on Internships, and the Internship Review Committee; and a brief report on foreign physicians serving as interns and residents in approved hospitals.

The material presented in the report was compiled from information submitted by hospitals approved for intern and resident training. The number of interns and residents serving and the number of vacancies in the intern and resident staff quoted in the statistical tables indicate the situation as of Sept. 1, 1954. Accordingly, there is a difference between the statistics presented in the tables and those in the lists of approved services, since the latter refer to appointments for the year beginning July 1, 1956.

Following the report, there are published lists of hospitals offering approved internships and residencies. The first list is devoted to hospitals approved for intern training, in which hospitals are listed by city and state; information is included on the type of control, the total number of beds, annual admissions, availability of outpatient services, the autopsy rate, the length of the program, affiliated services, the stipend, and the number and type of internships offered. A second classification lists these hospitals according to types of internships offered. The second section lists the approved residencies according to medical specialty, giving statistical data for the particular service, the name of the chief of service, and other pertinent information similar to that included in the internship list. In addition, hospitals approved for resident training are listed on a geographical basis, giving the specialties for which each hospital is approved.

The Annual Report and the lists referred to above, together with information on all approved examining boards in the medical specialties, are reprinted annually as the Directory of Approved Internships and Residencies.[1] The Council will furnish copies of this directory upon request. The publication of this report and the lists of approved hospitals is made possible through the cooperation of the medical staffs and the administrators of hospitals in which approved intern and resident programs are conducted. The Council gratefully acknowledges their support and assistance in providing the statistical data on which this report is based.

The Council has collaborated with the following organizations in approving residency programs:

- Advisory Board for Medical Specialties
- American Academy of General Practice
- American Board of Anesthesiology
- American Board of Dermatology and Syphilology
- American Board of Internal Medicine
  - Subspecialty Board on Allergy
  - Subspecialty Board on Cardio-Vascular Diseases
  - Subspecialty Board on Gastroenterology
  - Subspecialty Board on Pulmonary Diseases
- American Board of Neurological Surgery
- American Board of Obstetrics and Gynecology
- American Board of Ophthalmology
- American Board of Orthopedic Surgery
- American Board of Otolaryngology
- American Board of Pathology
- American Board of Pediatrics
  - Subspecialty Board on Allergy
- American Board of Physical Medicine and Rehabilitation
- American Board of Plastic Surgery
- American Board of Preventive Medicine
- American Board of Proctology
- American Board of Psychiatry and Neurology
- American Board of Radiology
- American Board of Surgery
- American Board of Urology
- Board of Thoracic Surgery
- American College of Physicians
- American College of Surgeons

The Council expresses its appreciation to these organizations for their invaluable assistance, active participation, and continuing interest in the residency approval program.

The Annual Report is published for the information of the medical profession, medical educators, hospital administrators, and others interested in medical education at the internship and residency levels. It is hoped that the material contained in the report will be of value to young physicians and medical students in their efforts to further their training and in beginning their professional careers.

Internships

Table 1 presents a summary for the past 10 years of the number of hospitals approved for intern training and the number of approved internships. Last year, 844 hospitals offered 10,624 internships available as of July 1, 1955. This year there are 850 approved hospitals offering 11,048 internships, an increase of 6 approved hospitals and 424 internships. During the past 10 years, there has been an increase of 52 in the number of hospitals (7%), while the number of internships has increased from 8,584 to 11,048, or 29%. Ten years ago, the average number of interns per hospital was 10.8; in 1955, the average number is 12.9. It is significant to note that when the Council published its first list of approved hospitals in 1914, this list designated 603 hospitals that offered 3,095 approved internships, an average of 5.1 interns per hospital. In comparing these data with the 1955 figures, there is an increase of 41% in the number of approved hospitals, while the number of internships has increased 257%.

---

[1] Information on the examining boards in medical specialties will be published in THE JOURNAL, Oct. 1, 1955.

The disparity between the number of approved internships and the number of American medical school graduates available each year to fill them is gradually increasing. There were 6,960 such graduates in 1955. The disparity this year is therefore more than 4,000 internships, of which number less than one-half are filled by foreign medical school graduates. The Ad Hoc Committee on Internships in its final report to the House of Delegates recommended that hospitals offering intern training carefully reevaluate their individual needs for interns in an effort to reduce the number of vacant internships. It is of interest to note that 95% of currently approved hospitals will accept women medical graduates as interns and 19% of the approved hospitals offer dental internships; 79% are approved for residency training in one or more specialties. Hospitals offering approved internships located outside of continental United States include one in the Canal Zone, four in Hawaii, and five in Puerto Rico.

Table 1.—*Approved Hospitals and Internships, 1946-1955*

Year of Publication	No. of Hospitals	No. of Internships *
1946	798	8,584
1947	764	8,539
1948	807	9,118
1949	807	9,124
1950	799	9,398
1951	828	10,044
1952	865	11,467
1953	856	11,006
1954	844	10,624
1955	850	11,048

* U. S. Army and U. S. Navy hospitals and those outside the United States not included in 1946 and 1947 figures.

INTERNSHIPS, BY TYPE OF SERVICE

A breakdown of the number of approved internships by type of service is shown in table 2, including the number and percentage of those reported filled and vacant on Sept. 1, 1954. A total of 1,062 approved intern programs were offered in 850 hospitals. The total number of internships offered was 11,048. Of this number, 9,807, or 89%, were rotating in type. Straight internships, which included straight service assignments in the fields of internal medicine, pediatrics, surgery, obstetrics-gynecology, and pathology, showed the next largest number with 1,109 (10%) internships offered in this category. Mixed internships numbered 132, slightly more than 1%. In all instances, the percentage of internships offered in the three categories were the same as those for the previous year. The percentage of internships filled has increased slightly over last year's figures. Rotating internships were 82% filled on Sept. 1, 1954, as compared with a figure of 79% for the previous year. Mixed internships showed 82% against 68% for last year. Straight internships were 85% filled as compared with a previous percentage of 78.

Considering straight internships, there was an increase in those filled in internal medicine, pediatrics, and surgery. Internships in obstetrics-gynecology and patholog showed a low percentage of occupancy, probably du to the fact that the status of these straight services ha not been clarified following the action of the House o Delegates in December, 1952, recommending elimination of these two categories. The Council has subsequently taken action regarding the straight internship i obstetrics-gynecology, all hospitals approved for thi type of training having been notified that approval wil be discontinued effective June 30, 1957. Final actio concerning the straight internship in pathology is expected to be taken at the 1955 Interim Session of th American Medical Association in November.

The over-all figure for internships filled for 1954 1955 was 82%, an increase of 4% over 1953-1954. The number of vacant internships for all types dropped from 2,267 to 1,982, a decrease of 285. A further breakdown of these vacancies appears later in the report. The increased figure for internships filled is attributed to an increase of foreign medical school graduates serving as interns. The increase in American graduates, 99 more than in 1954, accounts for a part of the increase; however, there were approximately 2,000 more internships filled in 1954-1955 than there were American medical school graduates for that year.

INTERNSHIPS, BY TYPE OF HOSPITAL CONTROL

Table 3 shows the distribution of internships according to type of hospital control. Of the 11,048 approved internships, 629 (5.5%) were offered by federal hospitals; 3,404 (31%) by nonfederal governmental institutions; 6,954 (63%) were available in nongovernmental hospitals, and 61 (less than 1%) in proprietary hospitals. From the standpoint of positions filled on Sept. 1, 1954, three of the federal services group—the Public Health Service hospitals with an occupancy rate of 100%, Army hospitals with a rate of 99%, and Navy hospitals with 97% of their positions filled—and two of the nonfederal governmental group—county hospitals with 96% of their positions filled and city-county hospitals with an occupancy rate of 93%—were well above the average for all internships.

Table 2.—*Number of Internships, by Type of Service, 1954-1955*

Type of Internship	No. of Approved Programs	No. of Internships: Filled Sept. 1, 1954	Vacant Sept. 1, 1954	Percentage Filled

Grand totals	1,062*	9,066	1,982	82

* Number of internship programs in 850 approved hospitals.

The governmental-controlled hospitals, both federal and nonfederal, showed an increase in the percentage of positions filled over last year; in 1954-1955 figures were 89% in both instances, while those for the previous year were 82% and 84% respectively. The nongovernmental group of hospitals had an occupancy rate of 78% this year, an increase of 3% over last year. The proprietary hospitals showed the lowest percentage of positions filled, with a rate of 67%. Paralleling the increased percentage of intern positions filled, there was an actual increase in the number of interns on duty, 9,066 this year as compared to 8,275 last year. The average number of internships offered for federal hospitals was 15.7; the average number filled was 13.9. The figures for the nonfederal governmental hospitals were 26.6 and 23.6 respectively; for the nongovernmental group, 10.4 and 8.1; and for the proprietary hospitals, 6.1 and 4.1. The average number of internships available considering all hospitals was 12.9; the average number of internships filled was 10.6.

INTERNSHIPS, BY MEDICAL SCHOOL AFFILIATION AND BED CAPACITY

In this report and in the list of approved internships that follows, hospitals have been classified as "major teaching," "minor teaching," and "nonaffiliated," such classifications being based on the extent to which medical schools utilize these hospitals for undergraduate education. A "major teaching" hospital is one that is considered by the school as being a major unit in its undergraduate clinical clerkship program, while a "minor teaching" hospital is one utilized to a limited extent for undergraduate instruction. A "nonaffiliated" hospital is one not designated by a medical school as participating in such a program. Table 4 presents a statistical analysis of internships based on this classification.

The 140 hospitals designated as major units constituted 16% of approved hospitals for 1954-1955. They offered 4,017 internships, or 36%, of the total number. There were 73 minor teaching hospitals, or 9%, in which 849, or 8%, of internships were offered. By far the largest group of approved hospitals was that classified as nonaffiliated, of which there were 637, or 75%. This group offered 6,182 internships, or 56% of the total number.

The major teaching units had the highest internship occupancy rate—85%; the nonaffiliated group the lowest rate—80%. These rates were based on data as of Sept. 1, 1954. All three groups showed an appreciable increase in the percentage of internships filled over last year. The major units showed a 3% increase; the minor units had an occupancy rate of 81% as compared with 77% for the previous year; the nonaffiliated group showed a 4% increase. Occupancy rates varied from a low of 65% in hospitals with less than 200 beds to a high of 92% in hospitals with 500 or more beds; both these extremes occurred in minor teaching units.

The general trend indicates that the larger hospitals filled a higher percentage of their intern positions than did the small hospitals. This generalization is not directly applicable to the major teaching group, in which hospitals with less than 200 beds showed an occupancy rate of 87% while those classified as having 500 or more beds had a rate of 86%. The trend is borne out, however, if the data for hospitals of the same bed capacities are combined for major teaching, minor teaching, and nonaffiliated. The intern occupancy rates for this grouping are: hospitals of less than 200 beds, 77%; those having 200 to 299 beds, 76%; those with 300 to 499 beds, 83%; and those of 500 or more beds, 87%. Based on these statistics, it is evident that hospitals having a bed capacity of more than 300 filled an appreciably higher percentage of their internships than hospitals having less than this number.

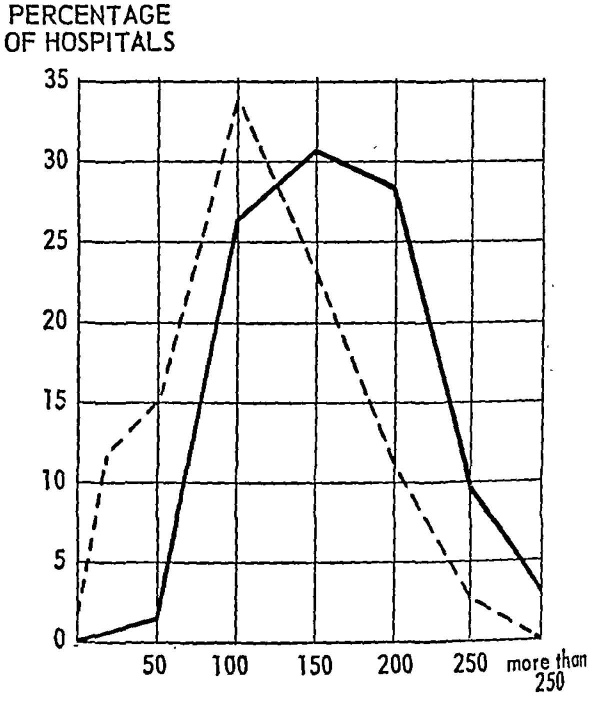
increase in the internship occupancy rate of 4% over last year; this increase is reflected in the rates for the census regions, each region in the continental United States having a higher rate than last year. Hospitals located outside the continental United States—those in the Canal Zone, Hawaii, and Puerto Rico—had 90% of their intern positions filled, the highest regional figure. The Pacific region had an occupancy rate of 88%, the highest in the United States. The region having the lowest percentage of intern positions filled was the East South Central region, with a rate of 72%. Occupancy rates varied in individual states from 100% in New Hampshire to 38% in Mississippi and Montana. These states, however, represent a small number of hospitals with one hospital approved in New Hampshire, while Montana and Mississippi each have two approved hospitals.

It is of interest to note that in the Middle Atlantic States—New York, New Jersey, and Pennsylvania—there are located more than one-fourth of all approved hospitals, one-fourth of the approved internships, and one-fourth of all interns on duty in approved hospitals. These figures correspond roughly to the proportion of the total population of the United States living in these three states. Of these three states, Pennsylvania showed the smallest percentage of internships filled, 75%, which was considerably below the national average. There are no hospitals approved for intern training in Idaho, New Mexico, Nevada, and Wyoming.



Monthly stipends, by medical school affiliation, excluding federal hospitals. Solid line indicates nonaffiliated hospitals (609) and dashed line indicates affiliated hospitals (201). Abscissa gives upper level of stipend range.

INTERNSHIP STIPENDS

A survey of the allowances offered interns in approved hospitals is shown in table 6. In tabulating these statistics, the number of hospitals paying a monthly stipend in the designated category is indicated in the first column under each listed stipend range. The number in the second, third, and fourth columns show the allowances given the intern in addition to the monetary stipend. Additional allowances offered refer to such items as laundry, uniforms, bonus, and health insurance.

All federal hospitals have been omitted from this listing. For purposes of comparison, hospitals have been classified as nonaffiliated and affiliated (major and minor teaching) groups. In the nonaffiliated group, which comprises three-fourths of the approved hospitals, the greatest concentration of cash stipends is centered in the classification $101-$150 (table 6). All hospitals in this group pay a cash stipend; only one pays $25 or less, and 17 pay more than $250. In addition to the stipend, 529 hospitals, or 87%, offer full maintenance; 61, or 10%, give partial maintenance; and 19 hospitals, or 3%, paid a cash stipend only. Other additional allowances are offered by 498 hospitals, or 82% of the group.

* Excludes federal hospitals.

In the affiliated group of 201 hospitals, the largest number pay stipends in the $51-$100 range. Four hospitals that have 300 or more beds give no monetary allowance. Only six hospitals in this group offer more than $200, and no hospital offers more than $250. A total of 161, or 80%, of these hospitals furnish full maintenance; 27, or 13%, furnish partial maintenance; and 13, or 7%, pay only a cash stipend. One hundred fifty-seven hospitals, representing 78% of this group, offer other prerequisites.

The average cash stipend offered interns by the nonaffiliated group for the year 1955 is $136 monthly; the amount paid by the affiliated hospitals is considerably less, the average being $87 per month. These averages are almost the same as last year's figures, which were $135 and $84 respectively. Although the average stipend in the nonaffiliated hospitals is $49 higher than that for the affiliated hospitals, the over-all internship occupancy rate for nonaffiliated hospitals for 1955 is 80%; that for the affiliated hospitals is 84%. It may, therefore, be concluded that the amount of the stipend is not the decisive factor for the graduating medical student in determining which internship he will select.

AUTOPSY RATES

A 25% autopsy rate on hospital deaths must be maintained by each hospital to qualify for approval for intern training. For the last reporting period (1954), all hospitals approved for internships submitted data from which their autopsy rates were computed. The average autopsy rate for these hospitals was 45%, or 20% more than the required minimum standard. The rate for federal hospitals was 61%; for other hospitals located in the United States, 44%, and for approved hospitals located outside the United States, 53%. Twenty-five hospitals (3%) had an autopsy rate of less than 25%. These hospitals must raise their autopsy rate for the next reporting period in order to qualify for continued approval. Table 7 includes a list of 20 federal and 20 nonfederal hospitals, approved for internships during the reporting period, that had the highest autopsy rates. The autopsy rate is considered an accurate index of the interest of the medical staff and the hospital administration in medical education and in scientific medical progress. Two-thirds of these listed hospitals were named in a similar table.[2]

AD HOC COMMITTEE ON INTERNSHIPS

The Ad Hoc Committee on Internships, a special committee composed of members of the House of Delegates of the American Medical Association, which was appointed in February, 1954, presented its final report last November.[3] This report was the result of an exhaustive study of the internship and its problems and included specific conclusions and recommendations. It was referred to the Council on Medical Education and Hospitals for its study and guidance. The Council presented a summary of the report to the House of Delegates, which was adopted in June, 1955.[4] The conclusions and recommendations of the Ad Hoc Committee on Internships, as presented by the Council and adopted by the House of Delegates, will be incorporated in a revision of the Essentials of an Approved Internship, to be published in January, 1956.

INTERNSHIP REVIEW COMMITTEE

The Internship Review Committee was established early in 1954. It is a permanent committee that acts in an advisory capacity to the Council. It recommends approval or disapproval of new and currently approved intern training programs, after a thorough analysis of the data submitted by the hospital and review of the report of the field representative of the Council that is submitted on completion of his survey of the program. In setting up the committee the Council has sought the cooperation of other national organizations concerned with intern education. In addition to members of the Council, the committee includes representation from the American Hospital Association, the Association of American Medical Colleges, the Federation of State Medical Boards in the United States, and the American Academy of General Practice. This committee continuously studies the problems and the content of the internship and makes recommendations to the Council that will assure the maintenance of high educational standards in approved hospitals and a year of sound clinical education and experience for the intern.

NATIONAL INTERN MATCHING PROGRAM

The National Intern Matching Program has completed four years of successful operation as the agent for appointing medical school graduates to internships in hospitals approved for such training by the Council on Medical Education and Hospitals. As a result of a detailed study of the policies and methods of the Matching Program, the Ad Hoc Committee on Internships concluded: "It is the opinion of this committee that the mechanical plan of matching interns and hospitals, as accomplished by the National Intern Matching Program, is more efficient than any other plan previously used and gives full effect to the freely expressed desires of both hospital and intern with complete objectivity. The committee approves of the Matching Plan."

The Ad Hoc Committee pointed out that there was some criticism of the program due, in all probability, to a misunderstanding of the method of operation. Acting on this information, the Matching Program began an intensive effort to provide detailed information regarding its activities to all concerned, including medical schools, approved hospitals, graduating medical students, and the medical profession as a whole. Explanatory material was distributed to interested individuals and organizations, outlining the policies and methods of operation of the Matching Program.

Other organizations interested in the internship along with the Council on Medical Education and Hospitals of the American Medical Association determine the policies under which the program operates. These are the American Hospital Association, the American Protestant Hospital Association, the Catholic Hospital Association, and the Association of American Medical Colleges. Also on the policy-making committee are two medical student representatives; one is appointed by the Student American Medical Association, the other is a student delegate at large. Each of the federal services conducting intern training programs has a liaison representative to the committee.

The National Intern Matching Program offers a method of intern placement consistent with American principles of individual freedom. Its basic principle of operation is to preserve freedom of choice for both the student and the hospital. The program does not approve, restrict, or control the internships offered by hospitals; it does not allocate or distribute interns. Its sole purpose is to facilitate the orderly placement of senior medical students in first year internships.

Hospitals participating in the program are limited to those approved by the Council on Medical Education and Hospitals for intern training. In the internship and residency section of THE JOURNAL, as prepared and published by the Council, hospitals offering approved internships that do not participate in the Matching Program are appropriately designated. The directory of participating hospitals, as distributed to all senior medical students by the Matching Program, is based on the Internship and Residency Number of THE JOURNAL; hospitals not participating in the program are not included in the reprint that is sent to the applicants for internships and to medical schools. The Matching Program sends to each senior medical student a pamphlet explaining in detail its purpose and its method of operation. Due to the efforts made to clarify the operations of the program, there is a better understanding of its work than previously existed. The program has been established as the official and generally accepted method of appointing interns.

---

[4] Report of the Council on Medical Education and Hospitals, Organization Section, J. A. M. A. 158: 53-54 (May 7) 1955.

For the year 1955-1956, more than 98% of the hospitals approved by the Council for intern training participated in the Matching Program. Approximately 96% of graduating medical students in 1955 registered in the program. Of the 6,713 students seeking appointments, 6,379, or 95%, were successfully matched. Of this number, 76% were matched with hospitals they had listed as their first choice; 14% were matched with hospitals they had listed as their second choice; and 10% were matched with hospitals they had listed as third choice or lower. A total of 334 students were not matched. The number of unmatched participants is attributed to the fact that in general they had applied to a limited number of hospitals. This resulted in restricting their chances for appointment, since the hospitals listed had filled their quotas with applicants whom they preferred or did not wish to appoint the particular student as intern.

Of the hospitals participating in the Matching Program, 16% completely filled their intern quotas; 52% partially filled their quotas, while 32% had no interns matched. Student participation in the Matching Program is expected to increase slightly for the year 1956-1957. The return of Matching Program Agreements, which have been distributed to approved hospitals for 1956-1957, indicate that at least an equal number of hospitals will participate in the program, as did last year.[5]

INTERNS AND RESIDENTS FROM FOREIGN COUNTRIES

According to a survey made by the Institute of International Education in September, 1954, there were 5,036 graduates of foreign medical schools in 83 countries serving as interns or residents in United States hospitals approved by the Council for this training.[6] This figure applied to citizens of other countries who intend to return to their home countries when their training assignments in the United States are completed; it did not include displaced persons, physicians coming to the United States to establish residence, or persons from United States possessions and territories; nor did it include foreign physicians serving in hospitals not approved by the Council. The 12 countries having the largest representation were: Philippines 776, Canada 520, Mexico 425, Germany 323, Turkey 253, Italy 242, Cuba 184, China 170, India 165, Korea 151, Greece 155, and Japan 139.

McCormack and Feraru[6] reported that of the total number of foreign physicians taking graduate training in this country, 3,275, or 65%, were serving as residents; 1,761 were interns. In tabulating statistics on the residents taking specialty training, it was found that the two largest groups were in general surgery and general medicine. Other fields in which training was being given were, in order, obstetrics and gynecology, pediatrics, pathology, psychiatry, anesthesiology, radiology, and otolaryngology.

These foreign physicians were found to be training in 42 states, the District of Columbia, Puerto Rico, Hawaii, and the Canal Zone. A total of 1,186, 24%, were concentrated in the state of New York. Other states having sizable numbers of these physicians were Ohio, 424; Massachusetts, 405; Illinois, 396; New Jersey, 348; Pennsylvania, 262; Missouri, 216; Michigan, 184; Maryland, 172; and California, 160.

The present policy of the Council is that graduates of foreign medical schools may be appointed to the intern or resident staff of a hospital without prejudice to its approved status. Responsibility for the evaluation of the applicant's qualifications must be assumed by the hospital, however, in those cases in which the applicant is a graduate of a school other than those included in the list prepared by the Council in collaboration with the Association of American Medical Colleges.[7]

The Cooperating Committee on Evaluation of Graduates of Foreign Medical Schools is presently studying the entire problem of foreign medical school graduates, with particular reference to graduate training for these physicians. The Committee is composed of representatives of the following interested organizations: the Council on Medical Education and Hospitals of the American Medical Association, the American Hospital Association, the Association of American Medical Colleges, and the Federation of State Medical Boards in the United States.

Residencies

The further expansion of residency training in the United States is reflected in the three tables included in this section of the Annual Report. The Council currently approves residency programs in 29 specialties and subspecialties. These programs are conducted in 1,181 general or special hospitals, the majority of which are also approved for intern training.

Early in 1953, the Council entered into discussions with the American boards in the medical specialties for the purpose of establishing joint committees with representatives from both organizations, the function of these committees being primarily that of responsibility for the evaluation and approval of residency programs in the specialty concerned. The forerunner for these committees was the Residency Review Committee for

[7] Medical Licensure Statistics for 1954, 53rd Annual Presentation of Licensure Statistics by the Council on Medical Education and Hospitals of the American Medical Association, J. A. M. A. 158: 292 (May 28) 1955.

Internal Medicine, which was originally established prior to World War II with representatives from the Council, the American Board of Internal Medicine, and the American College of Physicians. In 1950 a similar committee, the Conference Committee on Graduate Training in Surgery, was established. As in internal medicine, this committee included representatives from the college, as well as from the board, i. e., American College of Surgeons and American Board of Surgery. Residency Review Committees are now functioning in 16 separate fields including dermatology, internal medicine, neurological surgery, ophthalmology, orthopedic surgery, otolaryngology, pediatrics, physical medicine, plastic surgery, preventive medicine, proctology, psychiatry, radiology, surgery, and urology. A Residency Review Committee for General Practice with representatives from the American Academy of General Practice and the Council has been established during the past year. In four specialties, anesthesiology, obstetrics-gynecology, pathology, and thoracic surgery, the Council approves programs in concurrence with the board concerned, each organization however, taking action unilaterally.

---

* Surgery A includes programs leading to certification by the American Board of Surgery.

† Surgery B includes programs approved as offering training in general surgery in preparation for a residency in a surgical specialty.

The following section of the Report presents statistical data on the number of residencies by specialties and the number of residencies by type of hospital control and by bed capacities of the hospitals in which the training is conducted. The number of residencies filled and vacant represent the situation as of Sept. 1, 1954. The total number of residency appointments available increased from 23,628 reported last year to 25,486 this year, an increase of 8%. The number of residents serving also rose, from 18,617 during the year 1953-1954 to 20,494 during 1954-1955, representing a 10% increase. It can be assumed on the basis of available data, that the largest proportion of this increase was due to the number of graduates of foreign medical schools serving as residents in approved hospitals. The percentage of residencies filled remained comparatively the same with 80% filled this year, compared with 79% a year ago.

NUMBER OF RESIDENCIES, BY SPECIALTIES

Table 8 presents a breakdown by specialties of the number of approved programs, the number of first year appointments filled and vacant as of Sept. 1, 1954 and the total number of appointments filled and vacant for the same date. There were 4,834 separate residency programs conducted last year in 1,181 hospitals, offering a total of 25,486 appointments including 10,989 at the first year level.

The number of hospitals approved for training ranged from 11 offering residencies in contagious diseases 578 in internal medicine. The clinical specialties of ternal medicine, obstetrics-gynecology, pediatrics, p chiatry, and surgery, along with pathology and radiol accounted for slightly more than three-fourths of residencies offered, with 19,359 positions available these specialties out of a total of 25,486. There w less than 100 appointments in each of the follow specialties: allergy, 34; cardiovascular diseases, 68; c tagious diseases, 29; gastroenterology, 63; malign diseases, 34; plastic surgery, 72; preventive medici 71; and proctology, 31.

The percentage range of first year residencies fil varied from 32% of those in preventive medicine 94% of the programs offering a straight service gynecology. Similarly, for appointments at all levels, percentage filled in preventive medicine was the lowe 37%, while those in straight gynecology had the high occupancy rate, 98%.

Of those specialties constituting the majority of re dencies offered, pathology residencies showed the low occupancy rate for all years, 64% (first through fou year appointments) while surgery showed the highe 91%. Specialties in which more than 25% of residenci were vacant included the following: allergy, gene practice, malignant diseases, neurology, otolaryngolog pathology, physical medicine, preventive medicine, pro tology, psychiatry, and pulmonary diseases. In conside ing the relatively high vacancy rate in some of the specialties, particularly pathology and psychiatry, t proportionately large number of positions availab should be taken into account; 1,130 residents serving last year in approved pathology programs and 1,800 in psychiatric residencies.

As was the case last year, the percentage of all internships filled and that of all residencies were approximately the same, 82% in the case of internships and 80% for residencies. This fact again points up the similarity of the problem of house staffing, whether at the internship or residency level. In considering possible solutions, the singling out of internship vacancies as a separate problem may well be considered unrealistic, representing as it does only a part of the over-all question of house staffing.

RESIDENCIES, BY TYPE OF HOSPITAL CONTROL

A breakdown of residency appointments by type of hospital control is presented in table 9. Residency programs were offered in 117 federal hospitals, 314 other governmental (nonfederal) hospitals, 721 nongovernmental institutions, and 29 hospitals of a proprietary nature. The total number of residency appointments was about equally divided between governmental and nongovernmental hospitals with those in the former category offering 12,564 residencies while those in the latter had 12,922 appointments available.

Of the federal group, the Veterans Administration accounted for over three-fourths of the total, with 3,120 residency positions offered out of 4,089 for all federal hospitals. The occupancy rate for all federal hospitals, including the Veterans Administration was about 8% below that for the nation as a whole, 72% as contrasted to 80%. Comparable figures for last year showed 75% of residencies in federal hospitals filled and 79% for all hospitals. Considering appointments in all categories, the occupancy rate varied from 51% in U. S. Naval hospitals to 89% in city-controlled institutions. If first year appointments only are considered, the disparity in occupancy rates between federal and all other hospitals is even more marked. The U. S. Naval hospitals reported 38% of their first year appointments filled, the U. S.

Air Force 55%, the Veterans Administration 61%, the U. S. Army 64%, and other federal institutions 82%. The rates for other governmental (nonfederal) hospitals were well above these figures, ranging up to 89%, as were those in the nongovernmental group in which the rates ranged from 71% for church operated to 82% for the not-for-profit group.

In spite of the fact that the occupancy rate in federal hospitals fell below that of other approved hospitals, the number of residents serving in these programs increased over last year; there were 2,909 residents on duty in these hospitals as of Sept. 1, 1954 compared with 2,711 a year before. The seeming disparity between an increase in the number of residents serving and a decrease in occupancy rate in federal hospitals is due of course to the fact that 428 more residencies were available in these hospitals this year. This represents an approximate 12% increase for this group, as compared to a 7% increase over last year for all other hospitals.

NUMBER OF RESIDENCIES, BY HOSPITAL BED CAPACITIES

Excluding hospitals of less than 100 beds, the number of hospitals offering residency training are, roughly speaking, about equally divided into four categories, 100 to 199 bed capacity, 200 to 299, 300 to 499, and over 500 beds (table 10). The number of residencies offered in these hospitals however, varied considerably, with those in the 100 to 199 bed category offering 1,678 positions, or approximately 7% of the total and those of 500 beds and over, having 13,062 positions available or 52% of the total. Hospitals of bed capacities 200 to 299 and 300 to 499 offered an additional 10,297 residencies, or 40%. Hospitals of less than 100 beds and programs in institutions of undesignated bed capacities accounted for the remaining 1%.

A word of explanation may be in order regarding those hospitals of less than 100 beds, since they would appear to be of too small size to support a residency program. For the most part, they are hospitals of special type providing services in one or two specialties only such as children's orthopedic surgery; eye, ear, nose, and throat; obstetrics; pediatrics; and similar specialized fields. In these hospitals, the admission rate approximates that for a service in a larger general hospital. They offered a relatively insignificant number of residencies.

While the average number of residencies per hospital in the several categories listed may not be too important, it is of some significance in considering the distribution of residents. The averages are as follows: 100 to 199 beds, 7.4 residents per hospital; 200 to 299 beds, 11.6 residents; 300 to 499, 24 residents; and 500 and over, 44.8 residents per hospital. Since the total number of beds for all hospitals in each category has not been computed, the average number per resident cannot be accurately given. Using the mean number of beds for each category however, it can be estimated that the number of beds per resident vary from 12.5 in the 300 to 499 group, to 21.5 in the 200 to 299 category. A further variable in considering these rough estimates is of course the specialty itself; the number of beds that would be adequate for an obstetric service, for example, would be insufficient to support a program in orthopedic surgery.

On the basis of these incomplete data, however, it does not appear that there is a marked disproportion between the number of residencies and the size of the hospital. This generalization does not of course eliminate the possibility that there may be an "overloading" of residents in some hospitals. It does tend to show, however, that there is, on the average, a reasonable number of beds per resident in the majority of hospitals approved for residency training.

Résumé

An analysis of 10 statistical tables relating to internship and residency positions has been presented in this report, along with a brief review of the National Intern Matching Program and of the activities of the committees established to evaluate graduate training programs at the internship and residency levels.

As of Sept. 1, 1954, there were 1,364 hospitals sponsoring such programs; 159 were approved for intern training only, 515 for residency training only, and 690 that offered approved training in both categories. The number of internships rose from 10,624 offered a year ago to 11,048 this year, an increase of 4%. Similarly, the number of residencies increased during the past year from 24,741 to 25,486 or 3%.

A total of 29,560 physicians were on duty in approved hospitals during the past year, 9,066 in the capacity of interns and 20,494 as residents. The occupancy rate for internships in 1954 was 82% as compared to 78% a year before. That for residencies was 80%, approximately the same as reported in last year's report when 79% of appointments were filled.

The report points out that internship vacancies and residency vacancies are part of the same general problem. It calls attention also to the fact that an increasing number of graduates of foreign medical schools are serving in house staff positions in hospitals throughout the country. This development has been well recognized although the extent to which these graduates have been appointed has been, perhaps, less generally appreciated. Reference is made in the report to a committee, the Cooperating Committee on Evaluation of Graduates of Foreign Medical Schools, which has been established to study the problems presented in evaluating these graduates as potential interns and residents in hospitals in this country. Information on interns' stipends and hospital autopsy rates is presented along with analysis of internship appointments. Similarly, the section on residencies presents data on those programs, which from the standpoint of number involved, represent 70% of all house staff appointments, internships accounting for the remaining 30%. The report is factual in nature and is presented for the information of the profession and others interested in the graduate phase of medical education.

APPROVED INTERNSHIPS

Council on Medical Education and Hospitals of the American Medical Association
535 North Dearborn Street, Chicago 10

Revised to September 1, 1955

HOSPITALS, 865, INTERNSHIPS, 11,645

The following general hospitals, investigated and approved by the Council on Medical Education and Hospitals, are considered position to furnish acceptable intern training in accordance with standards adopted by the American Medical Association. Three pes of internships are approved by the Council—rotating, mixed, and straight:

1. A rotating internship is defined as one which provides supervised experience in internal medicine, surgery, pediatrics, obstetrics, d their related subspecialties, together with experience in laboratory and radiologic diagnosis.
2. A mixed internship is defined as one that provides supervised experience in two or more, but not in all, of the clinical visions named.
3. A straight internship is defined as one that provides supervised experience in a single department, although it may include nited opportunity for work in a related subspecialty. Straight internships are now approved in internal medicine, surgery, and diatrics. Straight internships in obstetrics-gynecology and in pathology are presently approved through June 30, 1957.

Hospitals approved for internships that are used by medical schools for undergraduate clinical clerkships on inpatient services ve been identified in the following lists by the symbols X and x. Hospitals have been identified with symbol X when a medical hool has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with the symbol when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program. Certain intern- ips in hospitals designated as teaching hospitals may not provide for assignments to teaching services. Other internships may ovide for only a portion of the internship period being spent on teaching services. Prospective interns desiring specific information ncerning internship assignments to teaching services in a hospital are advised to communicate with the dean of the medical school ith which the hospital is affiliated. Medical school affiliations are indicated by footnotes 10 to 88 placed immediately after the mbol X or x. The list of medical schools appears on page 283. The plus (+) sign indicates additional approval for residencies in ecialties, as shown in the Council's list of Approved Residencies and Fellowships. The beginning stipends for Federal hospitals have t been listed; they are established in accordance with government pay tables. When applying for internships in Air Force, Army, avy or Public Health Service hospitals, applications should be directed to the medical departments of the Air Force, Army, Navy, the United States Public Health Service and not to the individual hospitals. Although applications are made to the service rather an to the individual hospitals, all of the services ask students to list three hospitals in order of preference. Every possible effort made to place successful candidates in accordance with their desires. Because of the needs of the service it should be understood at students may, in some instances, be assigned to other hospitals than those for which they have indicated a preference.

Hospitals listed below (pages 261 to 282) make first year internship appointments through the National Intern Matching rogram, Inc. The number and type of internships as listed represent appointments for the intern year 1956-1957.

University of Alberta Hospital	Edmon
Royal Columbian Hosp.	New Westmin
St. Paul's Hospital	Vancou
Shaughnessy Hospital	Vancou
Vancouver General Hospital	Vancou
Royal Jubilee Hospital	Victc
St. Joseph's Hospital	Victc
Veterans' Hospital	Victc

ABBREVIATIONS AND NOTES

1. Appointments available to women applicants
2. Appointments restricted to women applicants
3. Appointments available to graduates of foreign medical schools. Details regarding requirements for appointment can be secured from the hospitals concerned.
4. Dental internships available
5. Available to citizens of the United States only
6. General Practice internships

+ The plus sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies and Fellowships.

ChurchRel	Church Related
ChurchOpr	Church Operated
CyCo	City and County
Corp	Corporation unrestricted as to profit
NPCorp	Nonprofit corporation
Part	Partnership
Req	Required
FM	Full maintenance
PM	Partial maintenance

Medical School Affiliations

Footnotes 10 to 88 refer to medical schools affiliated with hospitals for undergraduate clinical clerkships.

Hospitals have been identified with symbol X when a medical school has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with symbol x when a medical school has indicated that the hospital is used to a limited extent in the school's teaching rogram.
